DET NORSKE VERITAS

ENGLISH SUMMARY

Date of first issue: 2004-03-25	Project No.: CONNO63502365
Approved by: Magne Tørhaug Regional Leader	Organisational unit: DNV Consulting
Client: STATOIL ASA Stavanger	Client ref.: Karl Henrik Bryne

Summary:

This summary presents the results from the environmental monitoring at Region VI, Haltenbanken, 2003.

A total of 10 fields and 8 regional stations were included in the survey.

Sediments have been sampled from the following fields: Norne, Åsgard, Njord, Heidrun, Draugen, Garn Vest, Garn Central, Rogn Sør, Mikkel and Kristin. A total of 199 stations were investigated.

The main parameters in the investigation were:

- Macrofauna
- Grain size and organic content
- THC/ PAH/NPD/decalins
- Metals

The report is divided into 3 main reports: Main report (DNV-report no. 2004-0218), Norwegian Summary report (DNV-report no. 2004-0316, English Summary report 2004-0317), and Appendices report (DNV-report no. 2004-0312). Foldable maps for each of the fields showing station location are given in the Main report.

PREFACE

The environmental survey at Region VI in 2003 was carried out jointly by Det Norske Veritas and SINTEF.

The report presents the results of the chemical/physical and macrobenthic analysis of the seabed sediments from Region VI.

PersonnelField work:

Tor Jensen (DNV, Party chief)
 Sam-Arne Nøland (DNV)
 Thomas Møskeland (DNV)
 Tormod Hansen (DNV)
 Knut Hjelmseth (DNV)
 Liv Guri Faksness (SINTEF)
 Andreas Parslow (SINTEF)

Grain size distribution:

Oddveig M. Bakken, Liv-Guri Faksness, Inger Steinsvik

Total organic matter:

Nina Gjøs

Metals:

Håkon E. Larsen, Andreas Parslow, Karina Ødegård

 Øystein Stokland, Marine Bunndyr (Polychaeta, varia)
 Thomas Møskeland (Crustacea)
 Sam-Arne Nøland (Echinodermata)
 Per-Bie Wikander, Mollusca (Mollusca)
 Tormod Hansen (Polychaeta, varia)
 Siri M. Bakke (Polychaeta, varia)
 Helene Østbøll (responsible - sorting)

Preparation of report:

Sam-Arne Nøland (main report)
 Siri M. Bakke (macrobenthic fauna)
 Nina Gjøs (chemistry)
 Frøydis Ored (chemistry)
 Thomas Møskeland (univariate analysis)

Project Manager:

Sam-Arne Nøland

Verification:

Tor Jensen

The main part of the chemical analysis was performed at SINTEF Material and Chemistry. dep. Environmental Technology and Analysis.

The biological analysis were performed at DNV's Biological laboratory at Høvik.

 NORWEGIAN ACCREDITATION Nr. TEST 032	<p>The laboratories - SINTEF SINTEF Material and Chemistry. dep. Environmental Technology and Analysis. – are accredited by Norsk Akkreditering to perform chemical analysis, accreditation no. Test 032 og Test 091. The accreditation is in accordance with NS-EN ISO/IEC 17025.</p> <p>The accreditation includes methods for determination of total hydrocarbon content (THC), naphtalensr, phenanthrenes and dibenzotiofenes (NPD), polycyclic aromatic hydrocarbons (PAH), metals, total organic matter (TOM) and grain size distribution in sediments.</p>
 NORSK AKKREDITERING TEST 083	<p>The biological analyses were carried out at DNV's Biology Laboratory, Høvik. The laboratory is accredited by Norsk Akkreditering to perform sampling of marine sediments and analysis of macrobenthic fauna in accordance with the Activity Regulations, accreditation no. TEST 083. The accreditation is in accordance with NS-EN ISO/IEC 17025.</p>

1 SUMMARY AND CONCLUSIONS

This summary presents the main results from the environmental monitoring in Region VI, Haltenbanken, 2003. Det Norske Veritas performed the survey in co-operation with SINTEF.

The report presents the results from the chemical/physical analysis of seabed sediments and from the analysis of macrobenthic fauna.

The field work was conducted in two periods from the vessel S/V *Geobay* in the period 20th of May to the 8th of June and from the vessel *Viking Poseidon* in the period 26th to 27th of June in 2003.

The sediments are analysed for the following analytical parameters.

Analysis	Parameter
Sediment characterization	<ul style="list-style-type: none"> • Grain size distribution <ul style="list-style-type: none"> - Distribution of pelite (< 63µm) and sand (>63µm) - Cumulative weight% distribution from 63-2000µm - Median particle diameter (Md), standard deviation (SD), skewness (Sk) and kurtosis (K) - % TOM in the sediment
Chemical analysis	<ul style="list-style-type: none"> • Hydrocarbons <ul style="list-style-type: none"> - THC, sum C12-C35 olefins included - NPD, naphthalenes, phenanthrenes and dibenzothiophenes sum and single compounds - PAH, 16 EPA compounds sum and single compounds - Decalins, sum of C5-C8 alkyl decalins - Olefins, compounds in the area C14H28 to C20H42 • Esters • Ethers • Metals <ul style="list-style-type: none"> - Ba, Cd, Cr, Cu, Hg, Pb, Zn, Al and Li digestion by nitric acid and by hydrofluoric acid/aqua regia/boric acid

The 2003 survey at Region VI shows:

- The sediments at Region VI are partly dominated by silt & clay and partly of very fine sand.
- The total organic matter content in the sediments is relative high and varies from 1,7 % to 8,1 %.
- The chemical results are in agreement with the drilling history.
- The regional stations and the reference stations are still unaffected by the drilling chemicals - no contamination or elevated concentrations are found in these sediments.
- Relative high THC levels (>50 mg/kg) are found at Åsgard M, Heidrun, Njord and Mikkel. The THC concentrations are lower at Norne, Åsgard N, S and X, Garn Vest and Rogn Sør, and elevated THC levels are not found at Draugen, Garn Central and Kristin. The dispersal area varies, out to 250m from the installation at new fields to 2000m at Njord. The THC concentrations have increased at Heidrun, Mikkel and partly at Njord. At Njord one station still contains very high THC concentrations due to leakage of oil based drilling mud from *slipjoint* in 2000.
- Decalins are found in the sediments when drilling mud base oil is found.
- Olefins and esters from drilling fluids are not found in the sediments at Heidrun.
- Ethers from the drilling fluid Aquamul B II are found in the sediments at Heidrun, the same low concentrations as in 2000. The results indicate a slow degradation rate.
- Dispersion of drill cuttings and mud is illustrated by the barium results. Elevated Ba concentrations are found out to 500m at Rogn Sør, out to 1000m at Garn Vest and out to 2000m at the other fields. Generally the Ba concentrations are similar to previous surveys, however a decrease is found at Draugen and an increase is found at Norne, Heidrun, Garn Vest, Mikkel and partly at Njord.
- The concentrations of the heavy metals are low, and elevated levels are only found at some stations.
- The macro benthic fauna community in the region are in general healthy and undisturbed. The species composition at the Regional station 1 and 3 differ somewhat from the other Regional stations. At these stations there are relative fine sediment compared to the others. Analyses over year show that there have not been any considerable changes in the region in the period 1997 – 2003.

- Following stations are considered as disturbed:

- Station Heidrun-6 (50° /550m) together with Heidrun-7 (45° /1000m) and Heidrun-12 (120° /550m). There was a good correlation between fauna and a combination of the factors Ba, Cd, Pb og THC.
- Station DR24B (300° /250m) at Draugen was characterised as disturbed in 2000, and the analysis reveals that this is still the case. But the levels of Ba and THC are reduced since 2000.
- At Njord the stations NJ-6 ($157,5^{\circ}$ /500m) and NJ-13 ($337,5^{\circ}$ /250m) are disturbed. In addition the analysis indicate slightly disturbance in the fauna at the stations NJ-9 ($247,5^{\circ}$ /250m), 14 ($337,5^{\circ}$ /500m), NJ-1 ($67,5^{\circ}$ /250m), NJ-2 ($67,5^{\circ}$ /500m) and NJ-5 ($157,5^{\circ}$ /250m).

- At several fields in the region, changes in the species composition gives indications of an increased supply of organic material.
- The results from the present survey in 2003 are in agreement with the 2000 survey.

The main parameters and the variation at each field:

Regional stations	Variation	Main characteristics
THC (mg/kg)	2,6 – 4,7	The concentrations of hydrocarbons, barium and metals are low, and no elevated levels are found.
Ba (mg/kg)	88 - 182	
Diversity (H')	5,2 – 6,0	Undisturbed fauna

Norne	Variation	Main characteristics
THC (mg/kg)	4,0 - 25,7	Elevated THC levels out to 500m (NW) and 1000m (SW).
Ba (mg/kg)	500 – 3000	Elevated Ba levels out to 2000m. Lower THC levels than in 2000, and similar Ba levels.
Diversity (H')	4,4 – 5,2	In general a healthy and undisturbed fauna, a possible slightly organic influence at some stations.

Åsgard	Variation	Main characteristics
THC (mg/kg)	2,8 - 75,5	Elevated THC levels out to 500 - 1000m. Elevated Ba levels out to 500m at installations N, X and M and out to 2000m at S. At S the THC levels are decreased, and the Ba levels are similar to 2000.
Ba (mg/kg)	441 - 2310	
Diversity (H')	4,9 – 6,0	In general a healthy and undisturbed fauna, a possible slightly organic influence around S and X.

Heidrun	Variation	Main characteristics
THC (mg/kg)	2,7 - 76,9	Elevated THC levels out to 1000m, an increase since 2000.
Ba (mg/kg)	182 - 8140	Olefins and esters are not found. Ethers from Aquamul B II are found, same concentrations as in 2000. Elevated Ba levels out to 2000m, an increase since 2000. 1500 tonnes of baryte are discharged in the period 2000 - 2002
Diversity (H')	4,5 – 5,8	Disturbance in the fauna at station Hei-6 (50°/550m), but also at Hei-7 (45°/1000m) and Heidrun-12 (120°/550m).
Draugen	Variation	Main characteristics
THC (mg/kg)	2,6 - 5,1	Elevated THC levels are not found, but only one 250m station is analysed. Elevated Ba levels out to 2000m, and a tendency of a decrease since 2000.
Ba (mg/kg)	125 - 2710	
Diversity (H')	5,4 – 6,3	In general a healthy and undisturbed fauna. Station DR24B (300°/250m) are characterised as disturbed.
Garn Vest	Variation	Main characteristics
THC (mg/kg)	3,1 - 8,2	Low, but elevated THC levels out to 250m. Elevated Ba levels out to 1000m. A slight decrease of THC and Ba since the baseline survey in 2000.
Ba (mg/kg)	191 – 1090	
Diversity (H')	5,7 – 6,0	In general a healthy and undisturbed fauna. Some indications of supply of organic material in 500 and 1000m.
Garn Central	Variation	Main characteristics
THC (mg/kg)	3,1 - 5,6	Baseline survey. Elevated THC levels are not found. Low, but elevated Ba levels at all stations out to 2000m.
Ba (mg/kg)	400 – 702	
Diversity (H')	5,6 – 6,0	In general a healthy and undisturbed fauna
Njord	Variation	Main characteristics
THC (mg/kg)	3,0 - 3660	Elevated THC levels out to 2000m. Fresh drilling mud base oil at station NJ6, 157,5°/500m. Elevated Ba levels out to 2000m. Some increases and some decreases of THC and Ba since 2000. The leakage from <i>slipjoint</i> in 2000 still causes very high THC levels. Discharges of baryte in 2000, and some during the first six months of 2003 as well.
Ba (mg/kg)	109 – 6840	
Diversity (H')	2,8 – 6,1	NJ-6 (157,5°/500m) and 13 (337,5°/250m) is disturbed. Slight disturbance at NJ-9 (247,5°/250m), 14 (337,5°/500m), NJ-1 (67,5°/250m), NJ-2 (67,5°/500m) and NJ-5 (157,5°/250m).

Mikkel	Variation	Main characteristics
THC (mg/kg)	2,4 - 112	Elevated THC levels out to 500m. Elevated Ba levels out to 2000m. An increase of THC and Ba since the baseline survey in 2001. Drilling started in 2002, and 700 tones of baryte are discharged. High Cu concentrations are found at <u>one</u> station.
Ba (mg/kg)	150 – 3260	
Diversity (H')	5,4 – 5,9	Species rich and undisturbed fauna.

Rogn Sør	Variation	Main characteristics
THC (mg/kg)	2,1 - 11,1	Slightly elevated concentrations at a few stations, THC out to 250m and Ba out to 500m. A slight increase since the baseline survey in 2001. Drilling started in 2002, and baryte has not been discharged.
Ba (mg/kg)	99 - 314	
Diversity (H')	5,6 – 6,1	Species rich and undisturbed fauna. Possible some organic enrichment.

Kristin	Variation	Main characteristics
THC (mg/kg)	1,6 - 6,9	Baseline survey. Low THC concentrations, no contamination.
Ba (mg/kg)	89 - 1370	Low, but elevated Ba concentrations out to 1000m.
Diversity (H')	5,3 – 6,1	Species rich and undisturbed fauna.

2 INTRODUCTION

This report presents the results from the regional survey at Haltenbanken 2003. The purpose of the regional survey is to study the environmental effects from the petroleum activity for a greater area than the earlier platform specific surveys. The regional survey at Haltenbanken was first performed in 1997.

The report is divided in three parts. In the summary report (this) is the most important results presented, and in the main report (DNV-report nr. 2004 – 0218) the results are commented and discussed.

The appendix report (DNV – report nr. 2004 – 0312) contains:

- Appendix A – Survey report
- Appendix B – Test report – sampling/biology
- Appendix C – Chemical results
- Appendix E – Survey program

In the region the following fields are included:

Table 2.1. Fields and installations included in the regional survey 2003.

Field	Operator
Norne	Statoil
Heidrun	Statoil
Åsgard	Statoil
Mikkel	Statoil
Kristin	Statoil
Draugen	Shell
Garn Central	Shell
Garn Vest	Shell
Rogn Sør	Shell
Njord	Hydro

The area included in the regional survey is shown in figure 2.1.

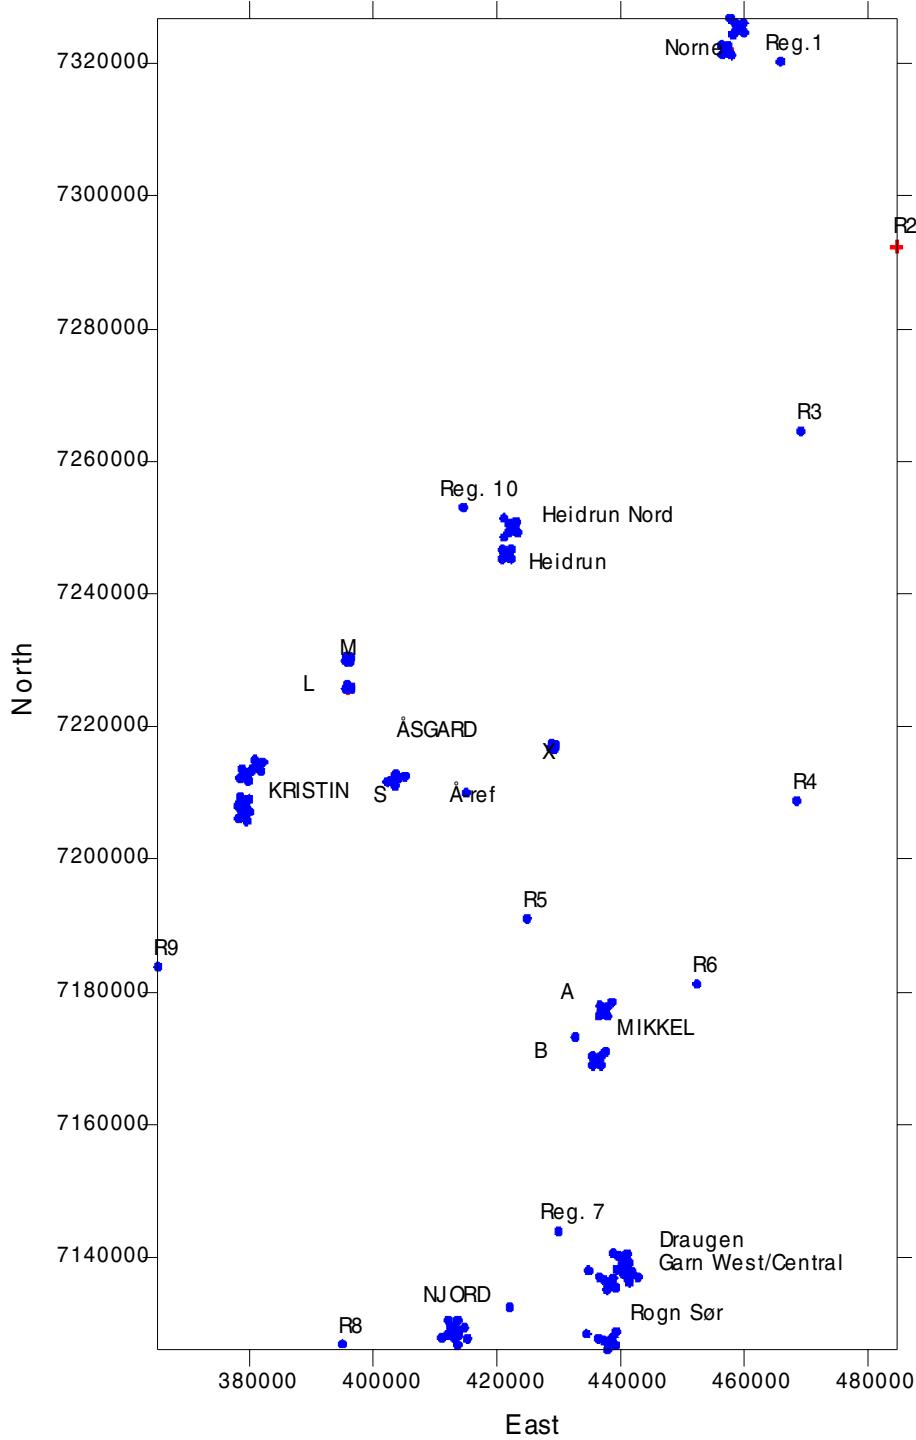

Figure 2.1. Overview of the fields included in his regional survey. Regional stations are marked R1 to R10. Some reference stations also functions as regional stations. Regional station R2 is excluded from the programme in 2003.

ENGLISH SUMMARY

Table 2.2. gives an overview of the number of stations at each field where biological and chemical sampling was performed.

Table 2.2. Total number of stations and analysis included in the regional survey at Haltenbanken 2003.

3 FIELD WORK AND METHODS

The field work was performed by DNV in cooperation with SINTEF using the vessel S/V Geobay in the period 20th of May to 8th of June and the vessel Viking Poseidon from 26th of June to 27th of June. Sampling and analysis are done with reference to activity regulation (OD, SFT, Hi, 2001), appendix 1, *requirement to environmental monitoring of the petroleum activity on the Norwegian continental shelf – technical appendix 2, Sediment monitoring* and DNV procedures for this kind of work. Deviation from the regulations is described in chapter 3.4. It is prepared a separate survey report, see appendix A in the Appendix report (DNV report 2004 – 0312). The survey report contains a complete overview of the sampling programme, included stations coordinates (UTM and degrees/minutes), water depth, date and time for the sampling, volume of sediment used in the soft bottom analysis, the number of unsuccessful shot, colour and some comments.

The sediments are analysed for the following analytical parameters.

Analysis	Parameter
Sediment characterization	<ul style="list-style-type: none"> • Grain size distribution <ul style="list-style-type: none"> - Distribution of pelite (< 63µm) and sand (>63µm) - Cumulative weight% distribution from 63-2000µm - Median particle diameter (Md), standard deviation (SD), skewness (Sk) and kurtosis (K) - % TOM in the sediment • Total organic matter
Chemical analysis	<ul style="list-style-type: none"> • Hydrocarbons <ul style="list-style-type: none"> - THC, sum C12-C35 olefins included - NPD, naphthalenes, phenanthrenes and dibenzothiophenes sum and single compounds - PAH, 16 EPA compounds sum and single compounds - Decalins, sum of C5-C8 alkyl decalins - Olefins, compounds in the area C14H28 to C20H42 - Petrofree - Aquamul B II • Esters • Ethers • Metals <ul style="list-style-type: none"> - Ba, Cd, Cr, Cu, Hg, Pb, Zn, Al and Li digestion by nitric acid and by hydrofluoric acid/aqua regia/boric acid

4 RESULTS AND DISCUSSION

In the summary report are only the most important results and conclusions presented. More detailed results and discussions are presented in the main report (DNV, 2004, report nr. 2004 – 0218).

4.1 Regional stations

4.1.1 Grain size and chemical analysis

The sediments at the regional stations consist mainly of silt and clay, and the content varies from 57 % at Regional 9 to 92 % at Regional 1. Similar distribution was found in the previous survey in 2000.

The total organic matter content is relative high and varies from 3,9 % at Regional 5 and Regional 7 to 6,3 % at Regional 1. The results can not be compared directly with previous years as deeper sediment layers are analysed in 2003. The tendency is slightly lower values in the present survey.

The concentrations of hydrocarbons, barium and metals are low, and the sediments are not contaminated.

The THC content in the sediments varies from 2,6 mg/kg at Regional 6 to 4,7 mg/kg at Regional 8. The barium concentration varies from 88 mg/kg at Regional 6 to 182 mg/kg at Regional 10.

Additional metal analyses by use of hydrofluoric acid/aqua regia/boric acid are also performed on the sediments from the regional stations. The Ba concentrations are higher than by nitric acid digestion, and they vary from 375 mg/kg at Regional 6 to 504 mg/kg at Regional 8. The concentrations of the heavy metals are similar to digestion by nitric acid.

A limit of significant contamination (LSC value) at Region VI is calculated for each chemical parameter at a confidence level of 95 %. The LSC values cover the total region.

4.1.2 Biology

The benthic fauna community in the region could be characterised as healthy and divers.

The Shannon-Wieners diversity index (H') range from 5,2 (Reg-01) to 6,0 (Reg-09). Pielou's index of evenness was in general high with a range from 0,8 to 0,9.

Different fauna parameters are given in table 4.5.

Table 4.5. Depth, number of species (S) and number of individuals (N) per $0,5\text{ m}^2$, Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Regional stations 2003.

Station	Depth (m)	S	N	H'	J	ES100
REG-01 (Norne Ref.A)	388	78	625	5,2	0,8	38
REG-03	336	95	563	5,4	0,8	42
REG-05	263	86	338	5,6	0,9	47
REG-06	232	91	467	5,6	0,9	45
REG-07 (DR51Bref.A)	270	99	520	5,8	0,9	47
REG-08	335	89	497	5,7	0,9	46
REG-09	312	108	563	6,0	0,9	51
REG-10 (HEI-27ref.A)	332	109	590	5,8	0,9	48

The MDS plot from the similarity analysis at station level is shown in figure 4.1. At about 60 % similarity the stations divide in 3 groups. The distribution of the stations in group 2 and 3 are in little degree dependent of the depth and geography.

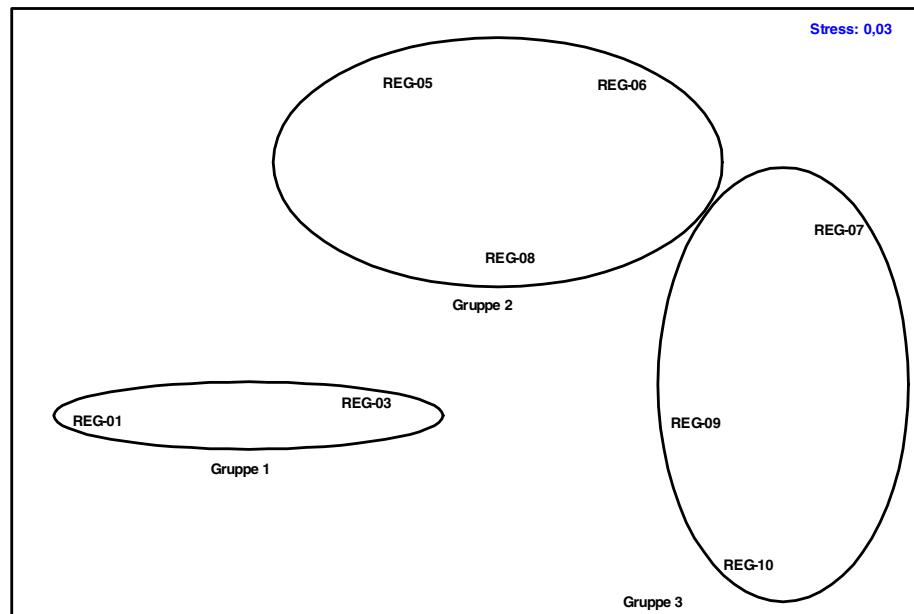

Figure 4.1. MDS-plot station level, Regional stations 2003

A bioenv analysis gave a high correlation (0,8) between fauna and a combination of the factors depth and grain size. The single factor which correlated best with fauna was the clay and silt fraction (0,6), followed by sand (0,5).

In particular station Reg-01, but also station Reg-03 separates from the others with a somewhat different species composition. However, these two stations have relative fine sediment compared to the others.

The dendrogram for the years 1994 - 2003, is shown in figure 4.2. Stations sampled in 1997, 2000 and 2003 separate in a main group at a similarity of about 60 %. The regional station sampled in 1994 separates most, while the station sampled in 1995 separates less from the others.

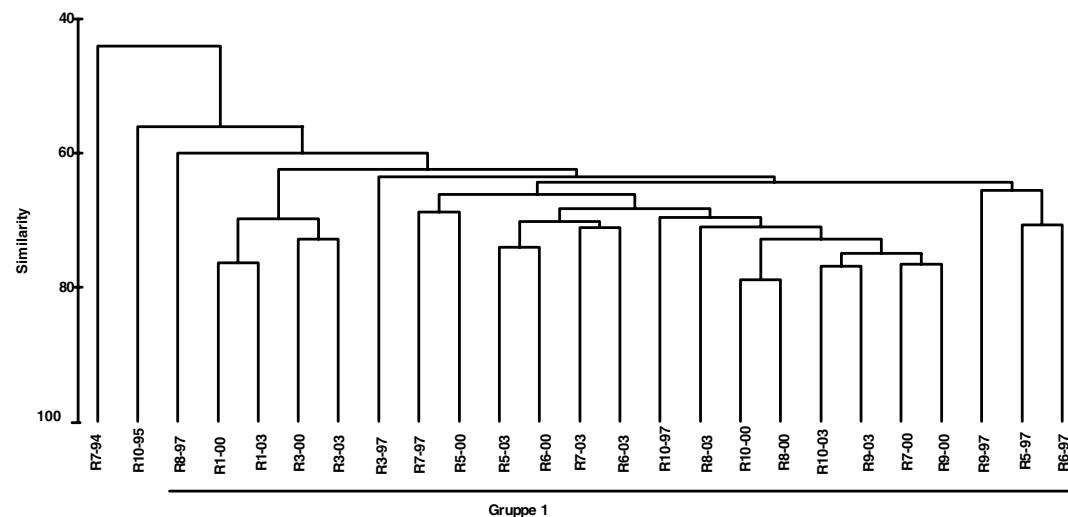

Figure 4.2. Dendrogram, Regional stations 1994 – 2003.

The results from the analysis over the years indicate very small changes since 1997.

4.2 Norne

4.2.1 Grain size and chemical analysis

The sediments at Norne consist mainly of silt and clay, from 73 % at station NOSW-07, 225°/500m to 96 % at station NONW-09, 225°/500m. The gravel content is low at all stations, up to 5 %. The results are similar to the 2000 results, except for station NONW-09, 225°/500m where the silt and clay content has increased from 61 % in 2000 to 96 % in 2003.

The total organic matter content varies from 4,7 % at station NOSW-12, 315°/1000m to 8,1 % at station NONW-02, 45°/500m and NONW-10, 225°/1000m. The results can not be compared directly with previous years as different sediment layers are analysed, 0-5cm in 2003 and 0-1cm previously. A tendency of same values at NW and slightly lower values at SW is observed.

At the NW templates the THC concentrations vary from 4,4 mg/kg at NONW-06, 135°/500m and NONW-10, 225°/1000m to 25,7 mg/kg at NONW-12, 315°/250m. The values are considerably lower than in 2000. The greatest difference is found at station NONW-09, 225°/500m where the THC concentration is reduced from 297 mg/kg in 2000 to 17,1 mg/kg in 2003. The 1-3 cm layer at station NONW-12 also contains slightly elevated THC values. Elevated concentrations are found out to 500m in the 225° direction and traces of elevated THC values are found out to 500m in the 45° and 315° directions. In the 135° direction no elevated THC concentrations are found at the innermost station at 500m.

At the SW templates the THC concentrations vary from 4,0 mg/kg at the reference station NOSW-ref. to 18,5 mg/kg at station NOSW-10, 315°/250m. The concentrations are decreased or they are at the same level as in 2000. At station NOSW-10 a THC concentration of 235 mg/kg was found in 2000. Elevated THC concentrations are found out to 500m in the 135° and 315° directions, out to 700m in the 20° direction and out to 1000 m in the 225° direction. However, the THC concentrations are low at these stations, below 10 mg/kg.

As previously low NPD and PAH concentrations are found at Norne. However, the concentrations are increased at station NOSW-10, 315°/250m where elevated levels are found. Previously high decalin concentrations are found at Norne. The decalin content is decreased since 2000, but the values are still high as 2,15 mg/kg is found at station NONW-12, 315°/250m. At this station the highest THC concentrations are found as well.

Elevated Ba concentrations are found in the sediments out to 2000m at both installations, and the concentrations are similar to the previous survey at most stations. At the NW template the Ba concentrations vary from 500 mg/kg at NONW-07, 135°/1000m to 2440 mg/kg at station NONW-12, 315°/250m. An increase is found at station NONW-09, 225°/500m, from 1060 mg/kg in 2000 to 2350 mg/kg in 2003. At station NONW-12, 315°/250m the Ba concentration is decreased in the top 0-1 cm layer and increased in the 1-3cm and 3-6cm layers.

At the SW templates the Ba concentrations vary from 147 mg/kg at the reference station NOSW-ref. to 3000 mg/kg at station NOSW-10, 315°/250m. At station NOSW-10 a decrease is found in the top layer, from 5900 mg/kg in 2000 to 3000 mg/kg in 2003. However, the concentration is increased in the 3-6 cm layer, from 335 mg/kg in 2000 to 1010 mg/kg in 2003.

ENGLISH SUMMARY

The concentrations of the heavy metals are low. Slightly elevated concentrations of Zn and Cr are found at all stations and of Cu at some stations. Values > LSC were also found at some stations in 2000.

The chemical results are in agreement with the drilling history. No discharges of oil containing drilling fluid have taken place at Norne since the previous regional survey. Previously large quantities of baryte have been discharged, and the discharges are now reduced, 362 tonnes in 2000, 78 tonnes in 2001 and 122 tonnes in 2002.

4.2.2 Biology

The fauna community at Norne is in general healthy and undisturbed.

The fauna at Norne differ somewhat from the fauna at fairly comparable regional stations. The difference is mainly due to a finer sediment type and a greater depth at Norne compared with the regional stations.

The Shannon-Wieners diversity index (H') range from 4,4 (NONW-12) to 5,1 (NONW-3, 6, and 15) at the NONW stations. Pielou's index of evenness was in general high with a range from 0,7 to 0,8.

At the NOSW stations the diversity index (H') range from 4,6 (NOSW-10) to 5,2 (NOSW-3). Pielou's index of evenness was in general high and range from 0,7 to 0,8.

Different fauna parameters are given in table 4.8.

Table 4.8. Depth, number of species (S) and number of individuals (N) per $0,5\text{ m}^2$, Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES_{100} , Norne stations 2003.

Station	Direction	Distance (m)	Depth (m)	S	N	H'	J	ES ₁₀₀

RefB			388	76	652	5,0	0,8	35

The MDS plot, figure 4.3, from the similarity analysis at station level shows that the fauna was relative similar at the Norne field. At 70 % similarity only one station, NOSW-8, separates from the main group (group 1). A division at about 70 - 75 % similarity separates the other stations in 4 sub groups.

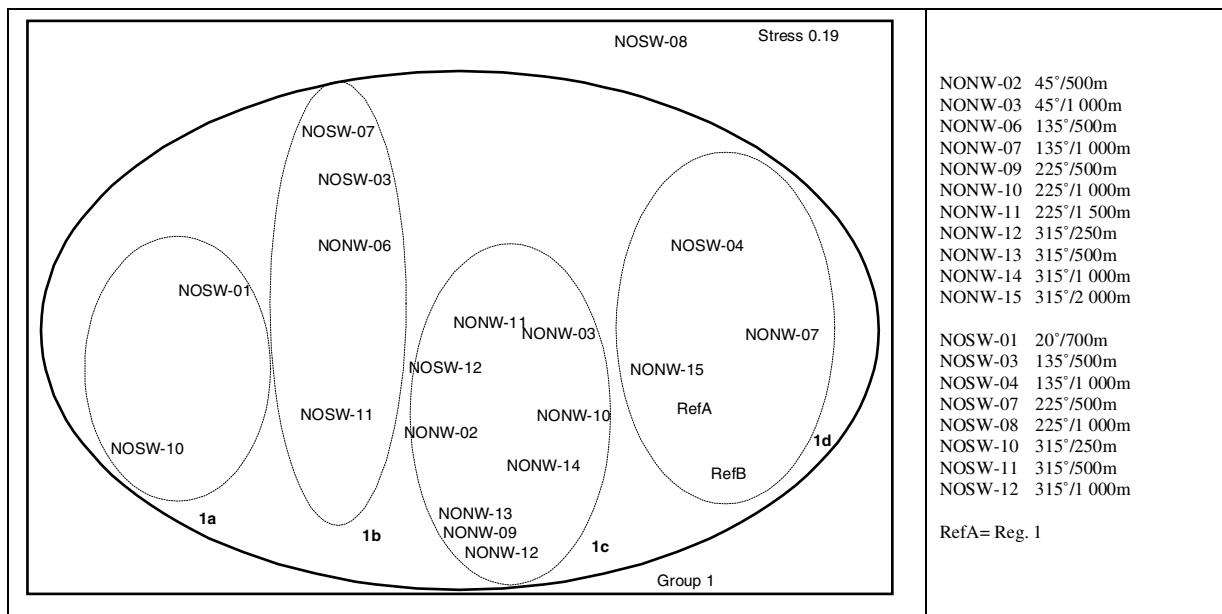

Figure 4.3. MDS-plot station level, Norne 2003.

The species composition and similarity analysis indicate a possible organic load at the NOSW stations close to the field centre in the 20° and 315° directions. NOSW-1 (20°/700m) and 10 (315°/250m). There were not found any correlation between fauna and environmental factors.

Figure 4.4 gives the dendrogram for the years 1995, 1997, 2000 and 2003. Only the NOSW stations are sampled all the years. The 1995 stations separate in group 2. Group 1 contains the other stations and could be divided in 4 sub groups, after years.

The trend analysis shows a general increase in the number of individuals within the most families. It was the increase of indicator species forward to 2003 which contributed most to the differences between the years. This indicates an increasing supply of organic materials in the area.

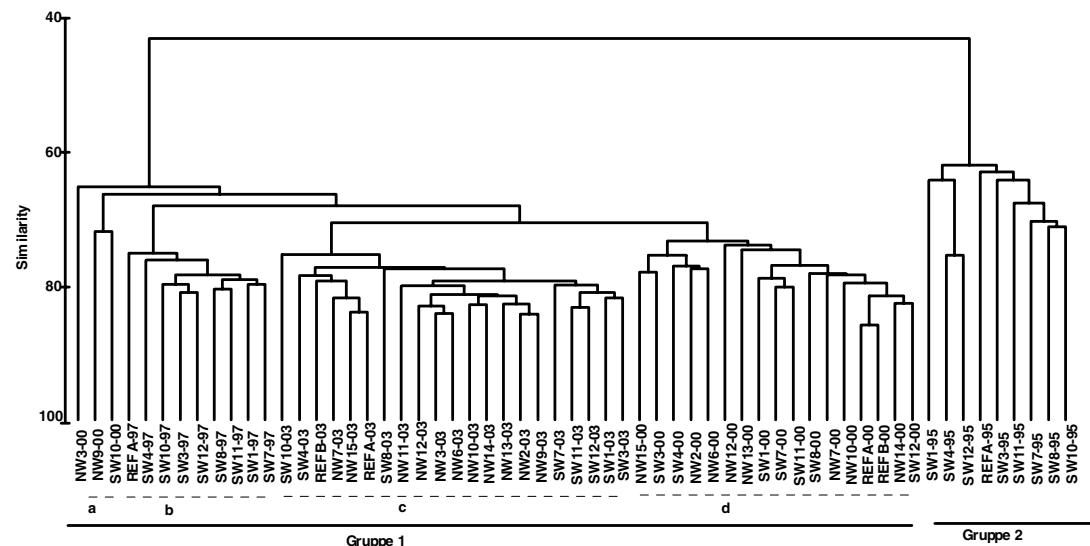

Figure 4.4. Dendrogram, Norne 1997-2003.

4.3 Åsgard

4.3.1 Grain size and chemical analysis

At Åsgard the installations N, S, X and M are included, and except for the baseline survey only the sediments at installation S are previously analysed.

The sediments at installations N and M at Åsgard are dominated of very fine sand, while the sediments at Åsgard S and Åsgard X are dominated of silt and clay. The silt and clay content at the field varies from 33 % at station N03, 240°/500m to 85 % at station S02, 160°/500m. The gravel content varies to a great extent, from no gravel at several stations to 13 % at station N01, 60°/500m. The variation is similar to the observations in 2000.

The total organic matter content in the sediments varies from 2,3 % at station N03, 240°/500m to 6,7 % at station S09, 75°/2000m. The lowest content is found at the N template (mean value 2,8 % at 500m) and the highest content is found at the S template (mean value 5,4 % at 500m). The results are similar to the 2000 results.

At installation N the THC concentrations vary from 2,8 mg/kg at station N04, 330°/500m to 14,9 mg/kg at station N03, 240°/500m. Only one of the five stations has elevated THC concentrations.

At installation S the THC concentrations vary from 3,4 mg/kg at station S07, 250°/1000m to 40,2 mg/kg at station S01, 75°/500m. The concentrations are decreased since 2000, and at station S01 a considerably reduction from 1210 mg/kg in 2000 to 40,2 mg/kg in 2003 is found. Only station S01 shows elevated THC concentrations.

At installation X the THC concentrations are low, and they vary from 3,7 mg/kg at station X03, 225°/500m to 9,8 mg/kg at station X01, 45°/500m. Only one station has slightly elevated THC values.

At installation M the THC concentrations vary from 3,0 mg/kg at station M04, 325°/500m to 75,5 mg/kg at station M01, 60°/500m. In addition to station M01, slightly elevated THC concentrations are found at station M03, 240°/500m (7,0 mg/kg).

Elevated THC concentrations are found out to 500m in one direction at the installations N (240°), S (75°) and X (45°), and out to 500m in two directions at installation M (60° and 240°).

The NPD and PAH concentrations are low. Slightly elevated values are only found in two of the samples. However, high decalin concentrations are found at station M01, 60°/500m, and decalins are also found at station X01, 45°/500m. A clear correspondence between the decalin and the THC results is observed.

Elevated Ba concentrations are found in the sediments at all stations except for the reference station. This means out to 2000m at template S and out to 500m at templates N, X and M. The Ba concentrations are relative similar across the survey area, although the lowest concentrations are found at template X. The Ba concentrations vary from 180 mg/kg to 2310 mg/kg.

The concentrations of the heavy metals are low at all four templates. Values slightly above the limit of significant contamination are only found at one station for Cu and two stations for Zn.

The chemical results are in agreement with the drilling history. No discharges of oil containing drilling fluid have taken place at Åsgard since the previous regional survey. The drilling includes one to five wells at each of the four templates, and minor acute discharges of oil based mud have occurred. Baryte has been discharged, less quantities in 2002 than in previous years.

4.3.2 Biology

The fauna community at Åsgard is in general healthy and undisturbed, and the regional stations do not separate from the Åsgard stations.

Shannon-Wieners diversity index (H') range from 4,9 (ÅS-X02) to 6,0 (ÅS-M01, 02, 04 and ÅS-N01). Pielou's index of evenness was high (0,8 and 0,9) at all stations.

Different fauna parameters are given in table 4.11.

Table 4.11. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Åsgard stations 2003.

Station	Direction	Distance (m)	Depth (m)	S	N	H'	J	ES ₁₀₀

The MDS plot from the similarity analysis at station level is given in figure 4.5. At a similarity of about 65 % the stations separates in 3 groups.

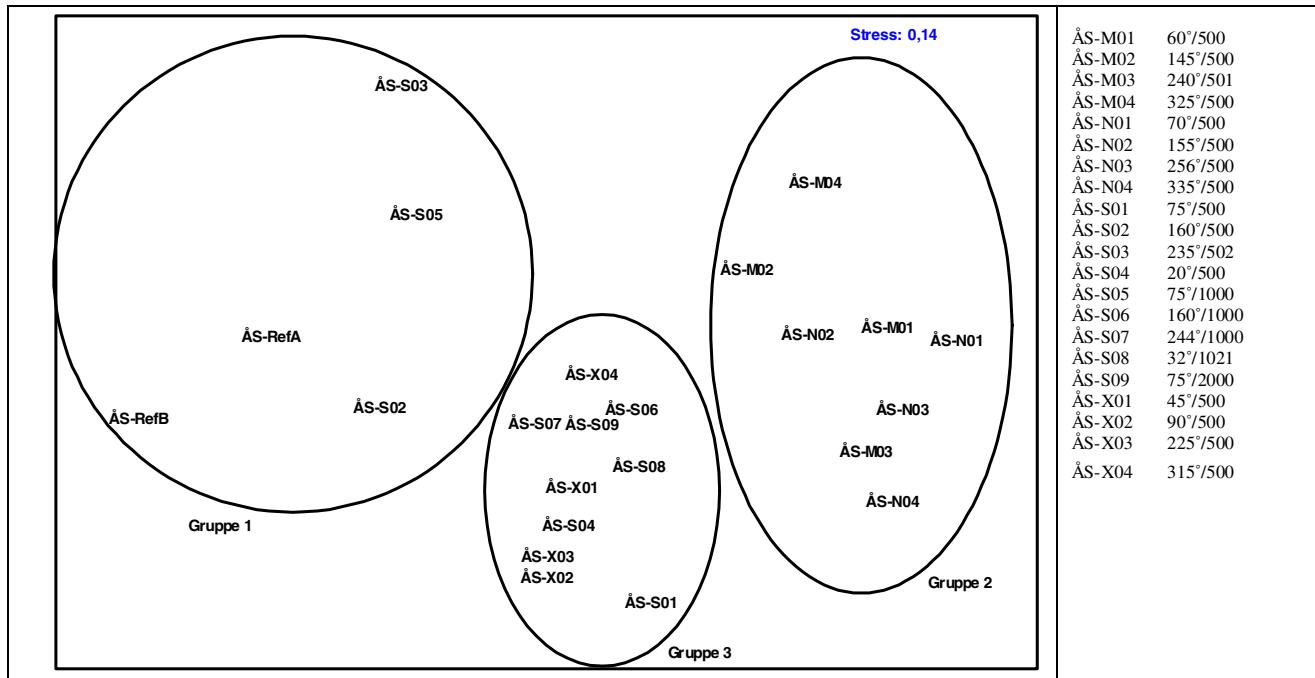

Figure 4.5 MDS-plot station levels, Åsgard 2003

The results from the similarity analysis indicate an organic load at the base frame S and X.

The bioenv analysis gave a correlation of 0,6 between fauna and a combination of the factors Ba, Cr and grain size. The single factor which correlated best was grain size (0,6). The correlations indicate some relations.

The dendrogram for the years 1996, 1997, 2000 and 2003 is given in figure 4.6. The dendrogram gives a separation into 5 main groups at about 60 % similarity.

The analysis indicates an increased supply of organic material in the area, with an increasing number of individuals.

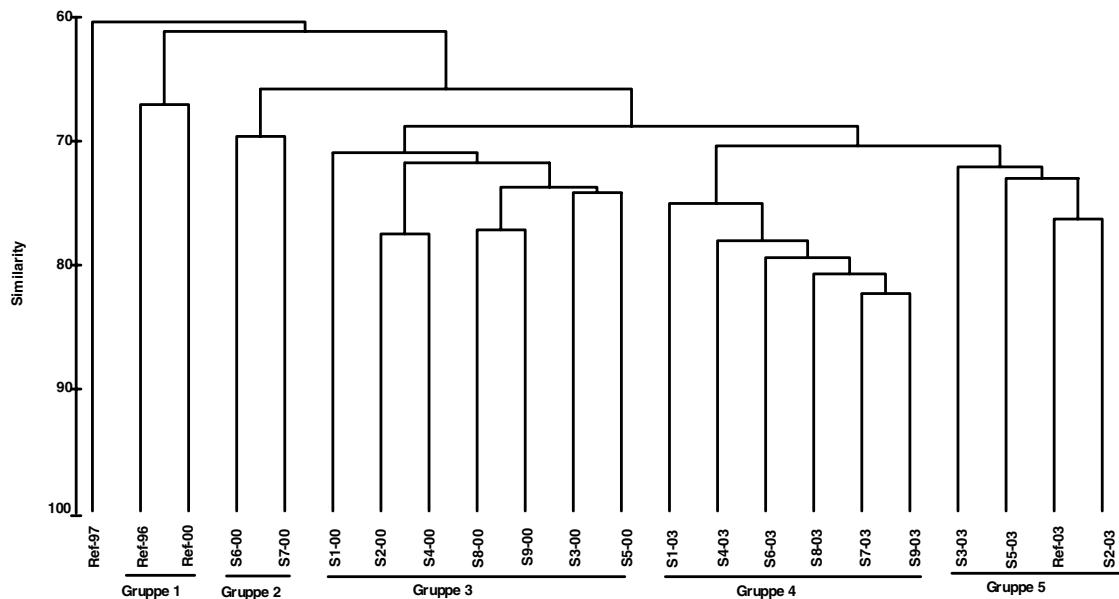

Figure 4.6. Dendrogram Åsgard, 1997 – 2003.

4.4 Heidrun

4.4.1 Grain size and chemical analysis

The sediments at Heidrun consist mainly of silt and clay that varies from 51 % at station HN-6, 225°/1000m to 86 % at station HN-1, 35°/500m. The gravel content is low, and the highest gravel content found is 2,7 %. The results are in agreement with the 2000 results.

The total organic matter content in the sediments varies from 3,3 % at station HN-9, 315°/1000m to 6,5 % at station HN-1, 35°/500m. Generally the results are similar to the 2000 results, but at some stations the content is decreased.

The THC concentrations vary from 2,7 mg/kg at station HEI-16, 315°/1000m to 76,9 mg/kg at station HEI-06, 50°/550m. An increase is found at several stations at 500m. Elevated THC concentrations are found at most of the stations at the main field, and this means out to 550m in the 225° and 305°/315° directions and out to 1000m in the 45°/50° and 120°/135° directions. Stations further out than 1000m are not analysed. At the templates further north only slightly elevated THC concentrations are found at two stations at 500m, station HN-1, 35°/500m and station HN-5, 225°/500m. At these templates stations out to 2000m are also included. It is likely that some of the elevated THC level results from drilling mud base oil, and that the main part of the THC contamination results from other discharges. Similar hydrocarbon profiles were also found in the 2000 survey.

Olefins are not found in the sediments, a further reduction since the 2000 survey when low concentrations were found at one station. The drilling fluid Petrofree, is not found in the sediments, and was not found in the 2000 survey either.

The drilling fluid Aquamul B II is found at all stations at the main field (TLP). The mean values vary from 0,3 mg/kg at station HEI-16, 315°/1000m to 65,4 mg/kg at station HEI-06, 50°/550m.

ENGLISH SUMMARY

At station HEI-12, 120°/550m a decrease is found, from 271 mg/kg in 1997, 119 mg/kg in 2000 to 17,9 mg/kg in 2003. A very uneven distribution and relative high concentrations in the sediments are observed. In the 3-6cm layer at station HEI-15, 305°/550m surprisingly high values are found (125 mg/kg). In general the conclusion is status quo, and the results confirm the slow degradation rate of the drilling fluid Aquamul B II.

The concentrations of NPD and PAH are low. Slightly elevated values are found at two stations, station HEI-06 and HEI-15. Decalins are found at station HEI-06, which also has the highest THC concentrations. One sample is analysed at station HEI-03, 225°/500m, and decalins and alkylated NPD compounds are found. This confirms that hydrocarbons from drilling mud base oil and also from other hydrocarbon sources are present.

High concentrations of Ba are found at Heidrun, and the values vary from 182 mg/kg at the reference station to 8140 mg/kg at HEI-06, 50°/550m. Elevated Ba levels are found at all stations except for the reference station, and this means out to 1000m and 2000m. At the templates an increase is found since the previous survey at all 500m stations. Otherwise a slight increase or similar levels as previously are found.

The concentrations of the heavy metals are low. At three stations slightly elevated concentrations of Cu and Pb are found, and elevated Hg concentrations, 0,30 mg/kg, are found at one station.

Generally the chemical results are in agreement with the drilling history. No discharges of oil containing drilling fluid have taken place at Heidrun since the previous survey in 2000. The main part of the THC concentrations found, results from other "hydrocarbons" than drilling mud base oil. In the period 2000-2002 more than 15000 tonnes of baryte have been discharged, 11 wells have been drilled at the templates and 1 well in the TLP area.

4.4.2 Biology

The fauna community at Heidrun is in general healthy and undisturbed and the fauna do not differ from comparable regional stations.

The Shannon-Wieners diversity index (H') range from 4,5 (HEI-06) to 5,8 (HEI-27A and 27B, HN-05, 06 and 09). Pielou's index of evenness was in general high and range from 0,7 to 0,9, with the lowest value at stations HEI-06 and 12.

Different fauna parameters are given in table 4.14.

The MDS plot, figure 4.7, from the similarity analysis shows in general a relative divers and healthy fauna community at Heidrun. However the analysis indicates disturbance in the fauna particular at station Heidrun-6 (50°/550m), but also at station Heidrun-7 (45°/1000m) and Heidrun-12 (120°/550m).

It was found a high correlation between fauna and a combination of the factors Ba, Cd, Pb and THC.

In figure 4.8 the dendrogram for the years 1995, 1997, 2000 and 2003 is given. The stations divide into 4 main group's relative independent of year at a similarity of about 55 %. The numbers of species and individuals have increased since 2000, but the diversity is relative unaltered in the same period. The changes are small and could be random and natural.

4.5 Draugen

4.5.1 Grain size and chemical analysis

The sediments at Draugen vary from silt and clay to fine sand. The silt and clay fraction varies from 36 % at station 24A, 325°/900m to 70 % at station 28A, 45°/1500m. The silt and clay fraction is increased at some stations and decreased at others. Gravel is found at all stations, and 13 % gravel is found at stations 24A, 325°/900m and 26B, 162°/500m. Compared to 2000, the gravel content is increased at some stations and decreased at other stations. As in 2000 the field is classified as very fine sand.

The total organic matter content in the sediments varies from 2,7 % at station 24A, 325°/900m to 4,9 % at station 27B, 162°/1000m. The values are similar to the 2000 results.

The THC concentrations vary from 2,6 mg/kg at station 24A, 325°/900m to 5,1 mg/kg at three of the stations. No elevated THC concentrations are found. At station 24B, 300°/250m the THC content is reduced from 20,3 mg/kg in 2000 to 4,9 mg/kg in 2003.

As in previous surveys the NPD, PAH and decalin concentrations are low, and elevated values are not found. This means that the decalin content at station 24B is decreased since 2000, in the same way as for THC.

The Ba concentrations vary from 125 mg/kg at the reference station 51B to 2710 mg/kg at station 24B, 300°/250m. A tendency of slightly decreased Ba concentrations is found at several stations. At station 24B, 300°/250m, a decrease from 5460 mg/kg in 2000 to 2710 mg/kg in 2003 is found. The layer samples at 1-3 cm and 3-6 cm also contain lower Ba concentrations compared to 2000. All stations show elevated Ba values except for the reference station 51B. Elevated Ba concentrations are found out to 2000m.

The concentrations of the heavy metals are low, and elevated values are not found.

ENGLISH SUMMARY

The chemical results are in agreement with the drilling history. No discharges of oil containing drilling fluid have taken place at Draugen since the previous survey in 2000. Baryte was discharged in the first six months of 2003, but no discharges in 2002. Probably the discharges in 2003 will not be found in the sediments across the field until future surveys.

4.5.2 Biology

The fauna community at Draugen is in general healthy and undisturbed. However, the fauna at Draugen separates somewhat from comparable regional stations, but it is still 60 % similarity between the groups.

The Shannon-Wieners diversity index (H') range from 5,4 (DR24B) to 6,3 (DR24A).

The species composition indicates a relative coarse sediment, with amongst others echinoderms among the dominant species at several stations.

Different fauna parameters are given in table 4.17

Table 4.17. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Draugen stations 2003.

Station	Direction	Distance (m)	Depth (m)	S	N	H'	J	ES ₁₀₀
DR21B	300	2 000	250	92	500	5,7	0,9	45
DR22B	300	1 000	245	111	427	5,9	0,9	51
DR24A	325	900	242	128	514	6,3	0,9	57
DR24B	300	250	253	143	1371	5,4	0,8	43
DR26B	162	500	256	106	542	6,0	0,9	51
DR27A	45	750	251	107	479	6,1	0,9	53
DR27B	162	1 000	264	109	559	5,9	0,9	51
DR28A	45	1 500	248	114	624	6,0	0,9	51
DR30B	325	500	250	113	783	5,6	0,8	44
DR31B	35	1 000	241	104	381	6,0	0,9	53
DR51BrefA (Reg 7)			270	99	520	5,8	0,9	47
DR51BrefB			270	93	503	5,7	0,9	47

In figure 4.9 the MDS plot from the similarity analysis is shown.

- The station DR24B separates somewhat in the analysis. At this station the indicator species *C. setosa* dominates in a high degree, the highest Ba concentration and a relative high fraction of sand in the sediment was also found at this station. The bioenv analysis gave a correlation of 0,6 between fauna and barium at the field.
- Indices and species composition indicate a healthy and divers fauna at the other stations.

Station DR24 B was also characterised as disturbed in 2000. Since then the levels of Ba and THC have decreased considerable.

Figure 4.10 gives the dendrogram for the years 1994, 1997, 2000 and 2003. The stations separate in two main groups. Group 1 contains stations sampled in 1997, 2000 and 2003 which further can be divided into sub groups after years. The exception is station 24B in 1997, 2000 and 2003 which separates into an own sub group.

The difference between the years is about 34-35 %. The stations sampled in 1997 differ most because of high individual numbers within the family Capitellidae (it was found a high number of the indicator species *Capitella capitata* at station 28A in 1997). Except from this, the differences are due to, in a high degree, variations within the bristle worms families *Amphinomidae*, *Ampharetidae*, *Sabellidae*, *Cirratulidae* and *Tricobranchidae* where the individual numbers varies between years, without any pattern. This is expected to be due to natural variations between years.

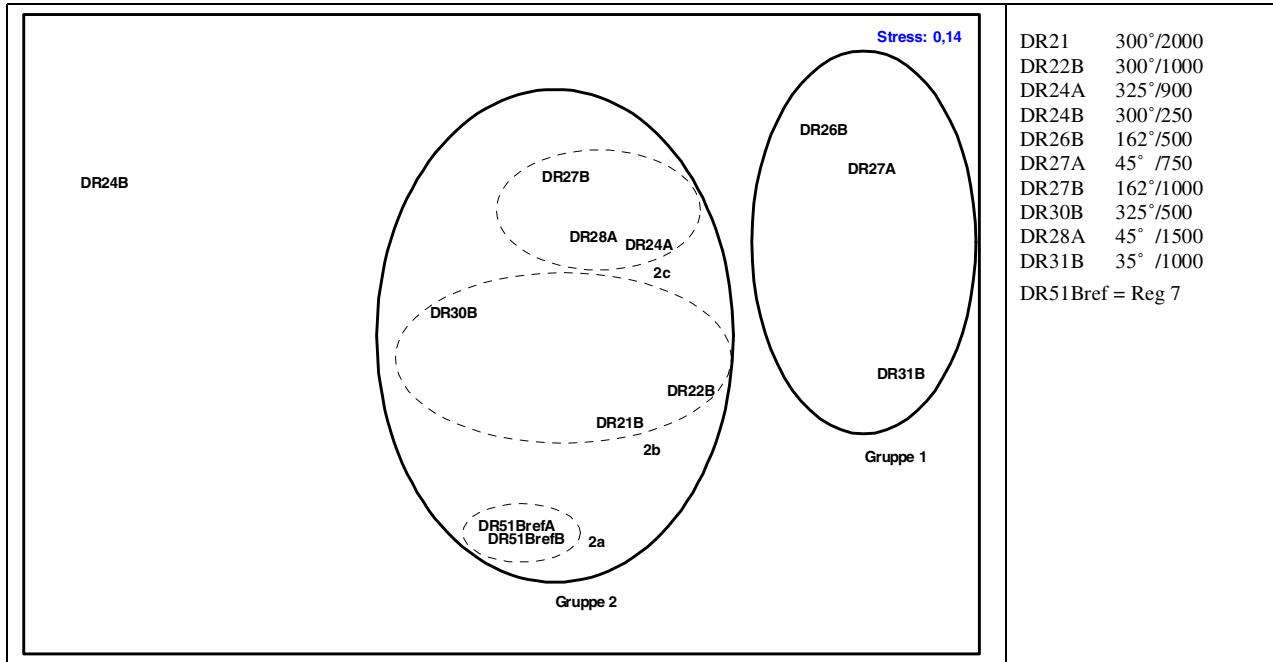

Figure 4.9. MDS-plot station level, Draugen 2003.

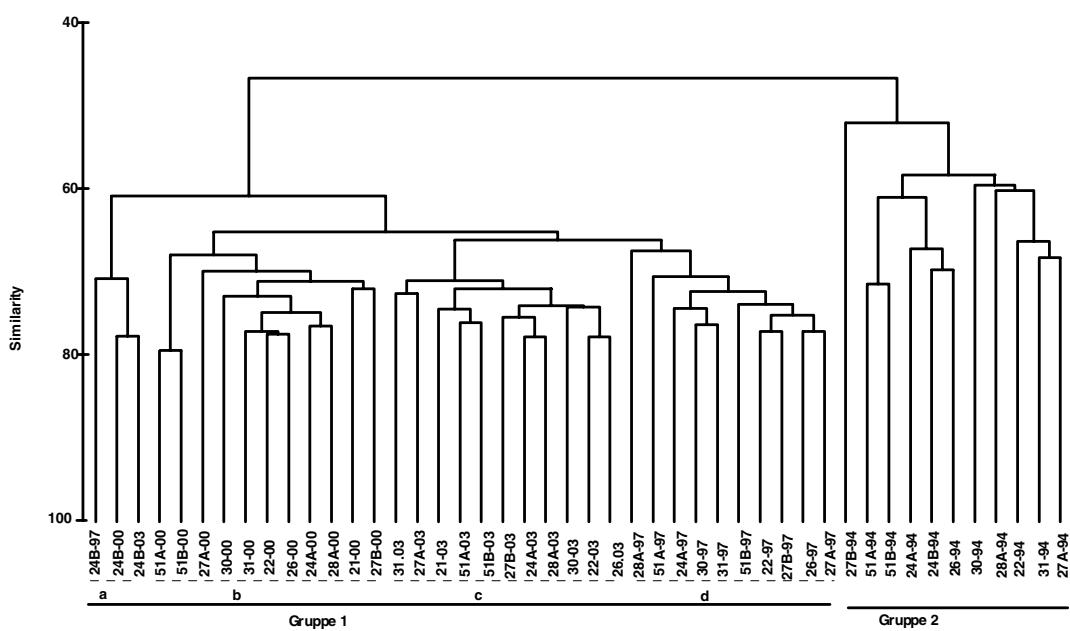

Figure 4.10. Dendrogram Draugen, 1994-2003.

4.6 Garn Vest

4.6.1 Grain size and chemical analysis

The sediments at Garn Vest vary from silt and clay to fine sand. The silt and clay fraction varies from 32 % at station GV13, 300°/2000m to 70 % at station GV7, 210°/250m. Gravel is found at all stations except for station GV7, an increase since 2000. The highest gravel content, 23 %, is found at station GV13, 300°/2000m. As in the baseline survey in 2000 the field is classified as very fine sand.

The total organic matter content in the sediments varies from 2,4 % at station GV12, 300°/1000m to 4,5 % at station GV10, 300°/250m. Compared to 2000 (0-1cm layer) the total organic matter content is lower at several stations in 2003 (0-5 cm layer).

The THC concentrations are low across the field, and they vary from 3,1 mg/kg at station GV13, 300°/2000m and station GV14, 300°/4000m to 8,2 mg/kg at station GV4, 120°/250m. A slight increase is found since the baseline survey in 2000. Although values above the LSC value are found at all the 250m stations and at two of the 500m stations, slightly elevated concentrations are only found at the 250m station in the 120° direction, station GV4.

The concentrations of NPD and PAH are low, and decalins are not found.

The Ba concentrations vary from 191 mg/kg at station GV13, 300°/2000m to 1090 mg/kg at station GV4, 120°/250m. A slight increase is found at some of the innermost stations. Slightly elevated Ba concentrations are found out to 1000m in three directions.

The concentrations of the heavy metals are low, and only a few elevated values are found.

The chemical results are in agreement with the drilling history. Two wells have been drilled at Garn Vest in 2001. Approx. 1 m³ of the base oil EDC 95-11 and 100 tonnes of baryte have been discharged in 2001.

4.6.2 Biology

The fauna community at Garn Vest is healthy and undisturbed with high diversity indices. In general there are relative high similarities between the Garn Vest stations and the regional stations.

The Shannon-Wieners diversity index (H') was high for all the stations and range from 5,7 (GW-08 and 11) to 6,0 (GW-03 and 12). Pielou's index of evenness was high at all stations (0,8 and 0,9).

Different fauna parameters are given in table 4.20.

Table 4.20. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Garn Vest 2003.

ENGLISH SUMMARY

The results from the similarity analysis, see MDS plot in figure 4.11, implies in general a healthy and divers fauna community.

A bioenv analysis gave a correlation of 0,6 between the fauna and a combination of the factors Cd and grain size. The best single factor was Cd and THC. The correlation coefficient indicates some relation.

In figure 4.12 the dendrogram for the years 2000 and 2003 is given. The analysis gives a trend with an increase of strong indicators as the bristle worm's *C. setosa* and *P. kefersteini* in addition to an increase of more sensitive suspension feeders from 2000 to 2003. The numbers of *C. setosa* and *P. kefersteini* at the individual stations are not very high, but this together with a general increase in the number of individuals could indicate an increasing supply of organic materials in the area.

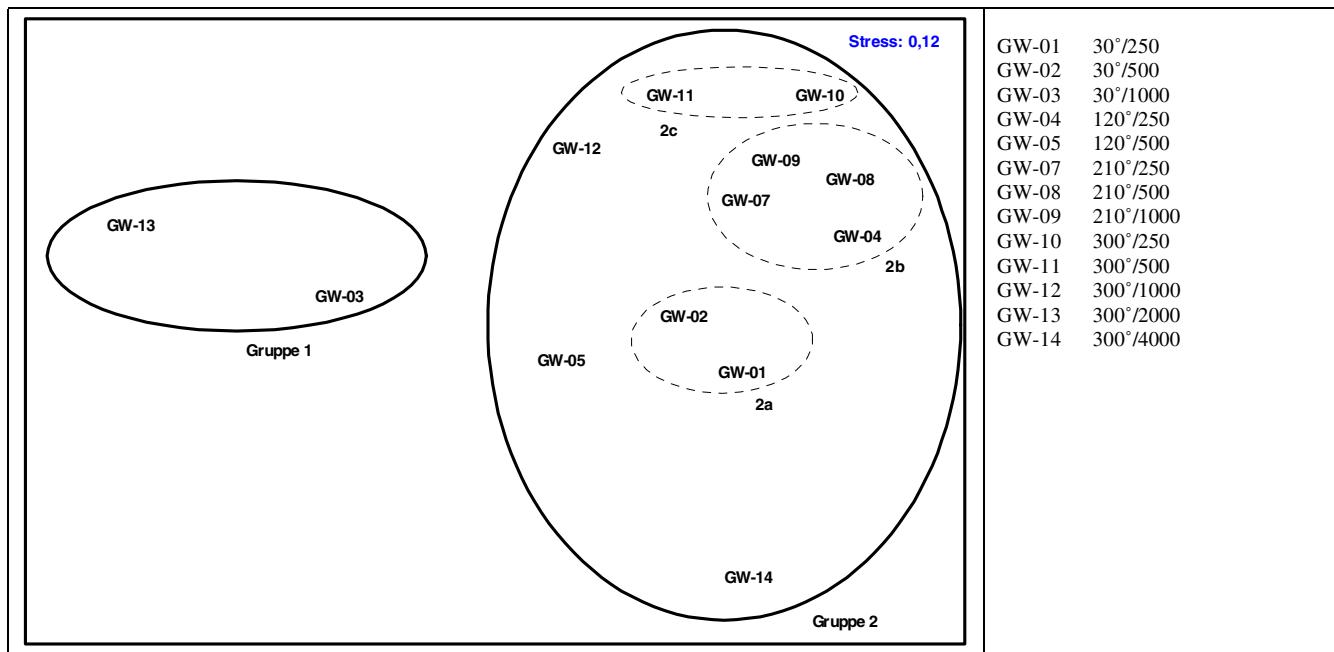

Figure 4.11. MDS-plot station level, Garn Vest 2003.

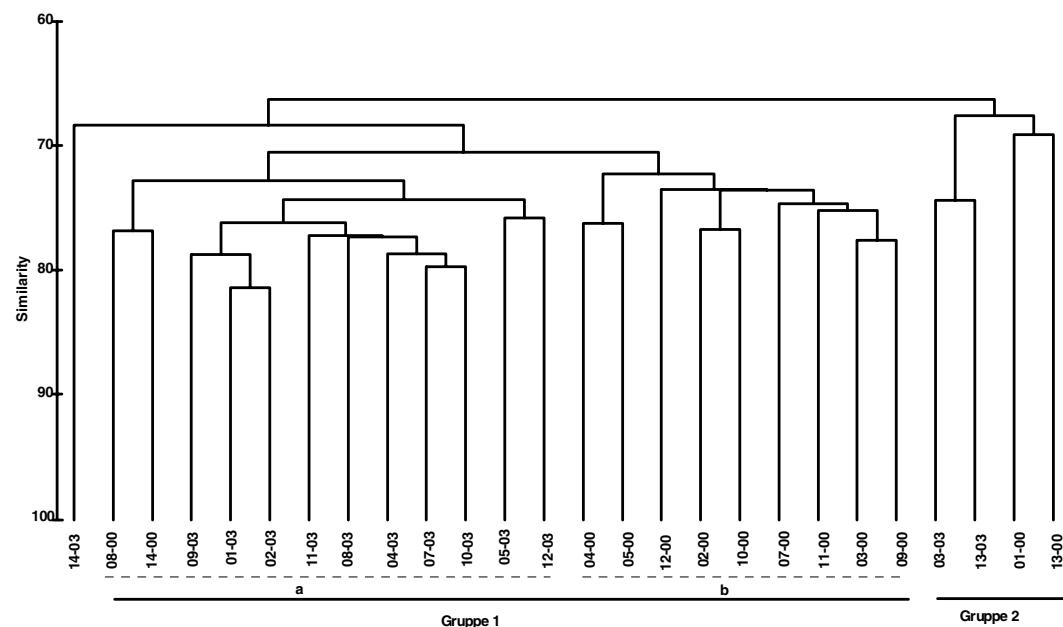

Figure 4.12. Dendrogram, Garn Vest 2000-2003.

4.7 Garn central

4.7.1 Grain size and chemical analysis

At Garn Central a baseline survey is performed. The silt and clay content varies from 43 % at station GC11, 300°/500m to 74 % at station GC10, 300°/250m. Gravel is found in the sediments at all stations. The highest content, 34 %, is found at station GC13, 300°/2000m.

The total organic matter content in the sediments varies from 3,1 % at station GC5, 120°/500m to 4,9 % at station GC10, 300°/250m.

The THC concentrations are low across the field, and they vary from 3,1 mg/kg at stations GC3, 30°/1000m and GC7, 210°/250m to 5,6 mg/kg at station GC13, 3000°/2000m. Elevated values are not found.

The concentrations of NPD and PAH are low, and decalins are not found.

The Ba concentrations vary from 400 mg/kg at station GC1, 30°/250m to 702 mg/kg at station GC9, 210°/1000m. Elevated values are found at all stations, but the concentrations are low compared to older fields in the region.

The concentrations of the heavy metals are low, and elevated values are not found.

Garn Central is situated north of Draugen. The highest Ba concentrations are found at the station nearest Draugen. It is not unlikely that the elevated Ba concentrations found at Garn Central may result from drilling performed at Draugen.

-: not analysed nd: not found Decalins are not found

4.7.2 Biology

The fauna community at Garn Central is healthy and undisturbed and do not differ much from comparable regional stations.

The Shannon-Wieners diversity index (H') range from 5,6 (GC-02) to 6,0 (GC-06). Pielou's index of evenness was high (0,9) at all stations.

The fauna community is according to the indices very healthy. The species composition is typical for relative coarse sediment.

Different fauna parameters are given in table 4.22.

The results from the similarity analysis imply an undisturbed fauna in the whole area. However, the species composition could indicate a greater supply of organic material in group 1. The differences are however small and could be random and natural. It was not found any correlation between fauna and environmental factors. See MDS plot, in figure 4.13.

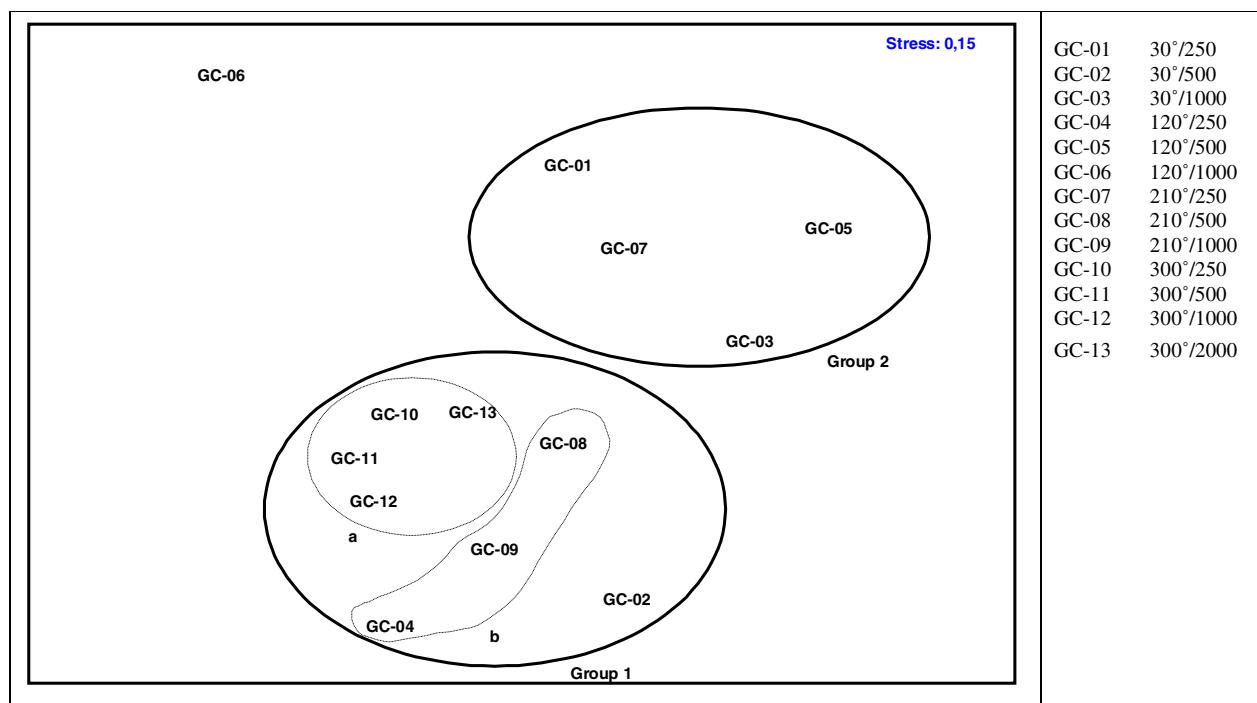

Figure 4.13. MDS-plot station level, Garn Central 2003

4.8 Njord

4.8.1 Grain size and chemical analysis

At Njord samples from 21 stations out to 2000m in 6 directions from the platform are analysed. The reference station is situated at 10 000m.

The sediments at Njord consist of silt and clay and also of very fine sand. The silt and clay content varies from 42 % at the reference station NJ17, 67,5°/10000m to 75 % at station NJ6, 157,5°/500m. Gravel is found at most of the stations, up to 8 %. The results are similar to the 2000 results.

The total organic matter content in the sediments varies from 2,8 % at station NJ2, 67,5°/500m to 4,4 % at station NJ11, 247,5°/1000m. The values are similar to the 2000 results.

The THC concentrations vary from 3,0 mg/kg at the reference station NJ17, 67,5°/10000m to 3660 mg/kg at station NJ13, 337,5°/250m. The THC values are similar or they are reduced since the 2000 survey. The exception is the two innermost stations in the 67,5° direction where an increase is found. Elevated THC concentrations are not found in the layer samples at 1-3cm and 3-6cm, a decrease at station NJ5, 157,5°/250m since 2000.

Station NJ6, 157,5°/500m differs from the other stations as a more fresh "drilling mud base oil" is found in the sediments. The station inside, NJ5, 157,5°/250m, does not show the same hydrocarbon profile, but has a more common profile of degraded "drilling mud base oil ". The results indicate acute discharges in the neighbourhood of NJ6.

The THC concentrations at the 1000m and 2000m stations are still low. However, drilling mud base oil is detected in the gas chromatograms from all stations except for three stations at 2000m.

As in previous surveys the concentrations of NPD and PAH are low. On the other hand, high concentrations of decalins are found at most of the stations, up to 265 mg/kg at station NJ13, 337,5°/250m. A clear correspondence is found between the decalin and the THC results. The concentration of decalins are also increased at stations NJ1, 67,5°/250m and NJ2, 67,5°/500m

The Ba concentrations vary from 109 mg/kg at the reference station NJ17, 67,5°/10000m to 6840 mg/kg at station NJ1, 67,5°/250m. Elevated Ba levels are found at most of the stations. High concentrations are found out to 1000m from the platform. At 2000m the concentrations are decreasing, but only the station in the 112° direction shows no elevated values. Compared to the 2000 survey an increase is found in the 67,5° direction and a decrease in the 157,5° direction.

The concentrations of the heavy metals are low. However, slightly elevated concentrations of Cu, Pb and Zn are found at station NJ13, 337,5°/250m.

The chemical results seem to be in agreement with the drilling history. Oil based drilling fluid has been used at Njord in the first six months of 2003, and an acute discharge of oil based mud has occurred, 94 m³ in February 2003. The leakage from *slipjoint* in 2000 resulted in very high THC concentrations in the sediments, and degradation of this oil will takes time. Large quantities of baryte have been discharged in 2000 and somewhat less in 2003.

4.8.2 Biology

The fauna community at Njord is in general healthy and undisturbed and do not differ from comparable regional stations.

- However, analysis and the species composition show that the fauna at station NJ-6 (157,5°/500m) and NJ-13 (337,5°/250m) is disturbed. In addition there are indications that the fauna at stations NJ-1 (67,5°/250m), NJ-2 (67,5°/500m), NJ-5 (157,5°/250m), NJ-9 (247,5°/250m) and NJ-14 (337,5°/500m) is slightly disturbed.

The Shannon-Wieners diversity index (H') was below 4 at station NJ-13 (337,5°/250 m) and NJ-6 (157,5° 500 m). At the other stations the diversity index H' range from 4,6 to 6,1. Pielou's index of evenness was high at the most stations and range from 0,5 to 0,9, with the lowest value at station NJ-13 (337,5° 250 m).

Different fauna parameters are given in table 4.25.

The MDS plot from the similarity analysis is shown in figure 4.14. Station NJ-6 and NJ-13 differed considerable from the other stations. The remaining stations divides into 2 main group at about 45 % similarity, of which group 2 consist of stations NJ-1, 2 and 5.

The similarity analysis indicates:

- The fauna at station NJ-6 (157,5°/500m) and 13 (337,5°/250m) is disturbed.
- A slight disturbance in the fauna at the stations in sub group 1a; NJ-9 and 14 (247,5°/250m and 337,5°/500m) and at station NJ-1 (67,5°/250m), NJ-2 (67,5°/500m) and NJ-5 (157,5°/250m) in group 2.
- The fauna at the other stations could be characterised as healthy and undisturbed.

It was found a relative good correlation between fauna and a combination of the factors Cr, Pb and THC. The single factor which correlated best (0,6) was Pb.

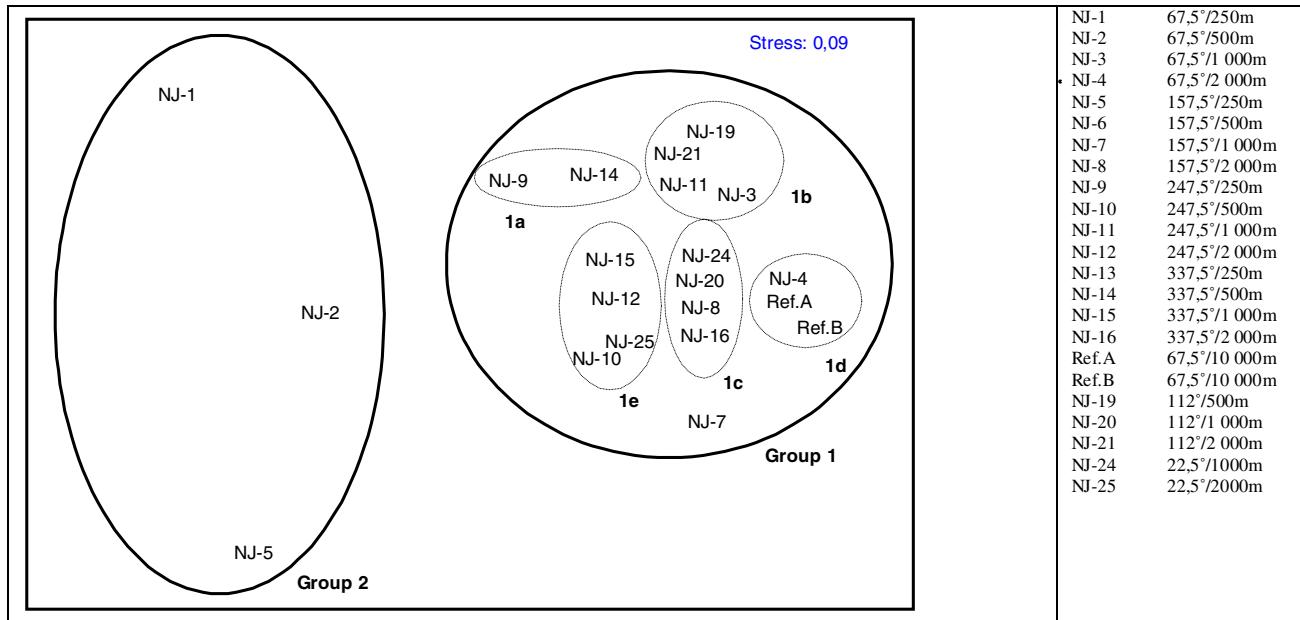

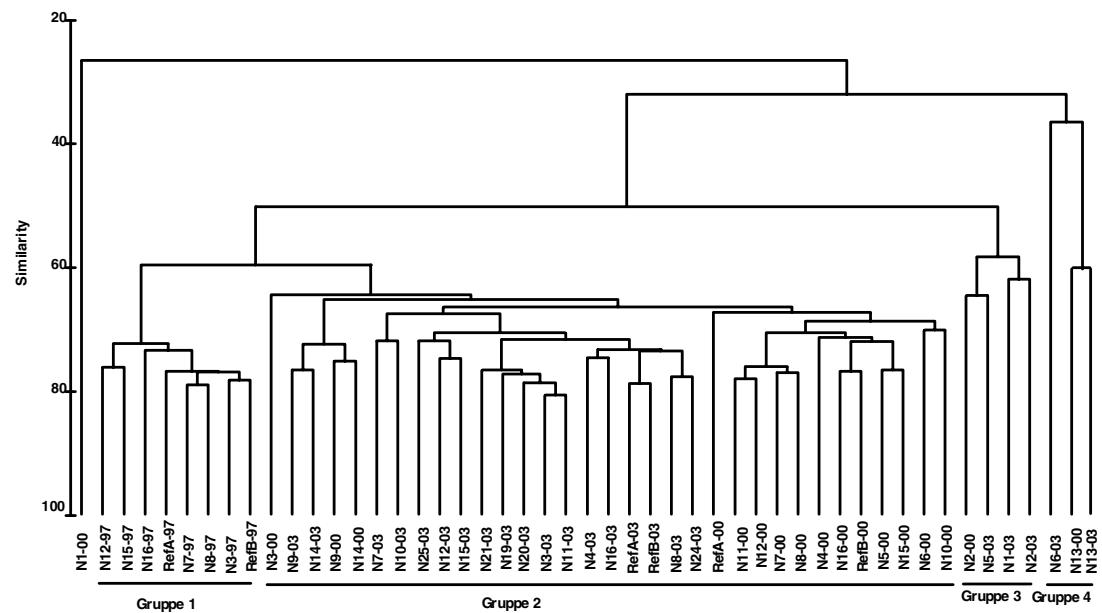

ENGLISH SUMMARY

In figure 4.15. the dendrogram for the years 1996, 2000 and 2003 is given. The stations divide into 4 groups at a similarity of about 30 %. Group 1 contains the 1996 stations, while group 2 contains most of the Njord stations from 2000 and 2003 which group at a similarity of about 70 %. The analysis shows that station NJ6-03 separates into the same group as station NJ13-00 and NJ13-03. This indicates an increased disturbance in the fauna at station NJ-6 since 2000.

Table 4.25. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Njord 2003.

4.9 Mikkel

4.9.1 Grain size and chemical analysis

The sediments at Mikkel show a great variation, from silt and clay to coarse sand. The sediments are somewhat finer at template B than at template A. At template A the silt and clay content varies from 20 % at station MIKA 07, 225°/500m to 64 % at station MIKA 10, 330°/1000m. At template B the silt and clay content varies from 32 % at station MIKB 10, 315°/1000m to 61 % at station MIKB 06, 135°/1000m. Gravel is found at all stations, up to 29 %. Some differences are observed since the baseline survey in 2001, however, the mean values are similar.

The total organic matter content is quite similar at the two templates. At template A the concentrations vary from 1,7 % at station MIKA 07, 225°/500m to 3,6 % at station MIKA 06, 135°/1000m and station MIKA 10, 330°/1000m. At template B the concentrations vary from 2,4 % at station MIKB 01, 45°/250m to 4,1 % at station MIKB 06, 135°/1000m. The highest content, 5,0 %, is found at the reference station MIKB 11A, 315°/5000m.

The THC concentrations are increased at some of the innermost stations at 250m and 500m since the baseline survey in 2001. At template A the concentrations vary from 2,4 mg/kg at station MIKA-04, 45°/2000m to 112 mg/kg at station MIKA-01, 45°/250m. Elevated THC concentrations that result from drilling mud base oil are found out to 500m in the 45° direction.

In addition elevated THC values are found at the 500m stations in the 225° and 330° directions, however, these hydrocarbons are compounds with higher bp. than the drilling mud base oil HDF 200.

At template B the THC concentrations vary 3,1 mg/kg at station MIKB-02 45°/500m to 52,7 mg/kg at station MIKB-05, 135°/500m. Elevated THC values are only found at station MIKB-05.

The NPD and PAH concentrations are low, and no values are considered as elevated. Decalins are found at four stations, up to 7,89 mg/kg at station MIKA-01, 45°/250m, the station with the highest THC values. The finding of decalins confirms the THC results and that drilling mud base oil is present in the sediments.

The Ba concentrations are increased at several stations out to 1000m, and elevated values are found at all stations except for the reference station. At template A the Ba values vary from 223 mg/kg at station MIKA-04, 45°/2000m to 2710 mg/kg at station MIKA-07, 225°/500m. An increase is found out to 500m in the 45° direction, in the 225° direction and in the 330° direction. At template B the Ba values vary from 150 mg/kg at the reference station MIKB-11A, 315°/5000m to 3260 mg/kg at station MIKB-05, 135°/500m. The Ba values are increased at the 500m station in the 135° direction and at the 1000m station in the 225° direction, but not in the 45° direction.

The concentrations of the heavy metals are low, but at one station, station MIKA-07, 225°/500m relative high Cu concentrations are found.

Generally the chemical results are in agreement with the drilling history. The drilling at Mikkel started in 2002, and 2 wells are drilled at template A and 1 well at template B by use of water based drilling mud. However, the results indicate that oil based drilling fluid has been used as well. 700 tonnes of baryte were discharged in 2002.

4.9.2 Biology

The fauna at Mikkel is very divers and healthy and the stations at Mikkel do not differ much from comparable regional stations.

The Shannon-Wieners diversity index (H') range from 5,4 (MIKA-10 and MIKB-11B) to 5,9 (MIKB-10). Pielou's index of evenness was relative high (0,8 and 0,9) at all stations.

Different fauna parameters are given in table 4.28.

The MDS plot from the similarity analysis at station level is shown in figure 4.16. Most of the stations divide into 2 groups at a similarity of about 65 %. Station MIKA-07 (217°/565m) and the second half of the reference station, MIKB-11B (315°/5000m), did not group.

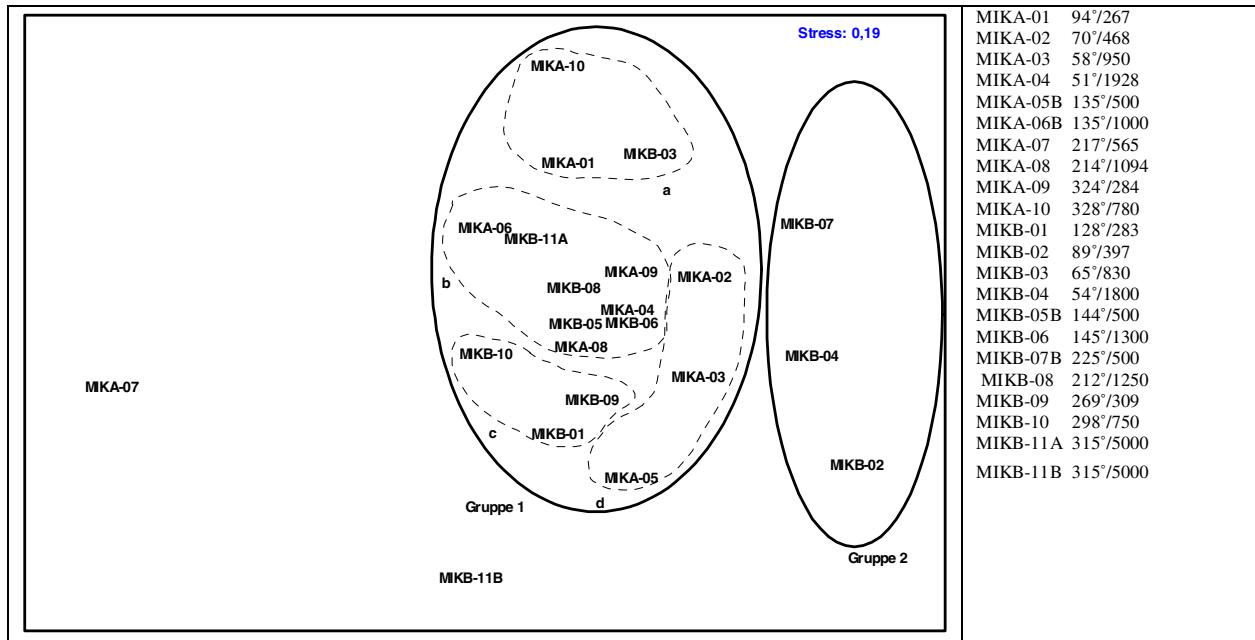

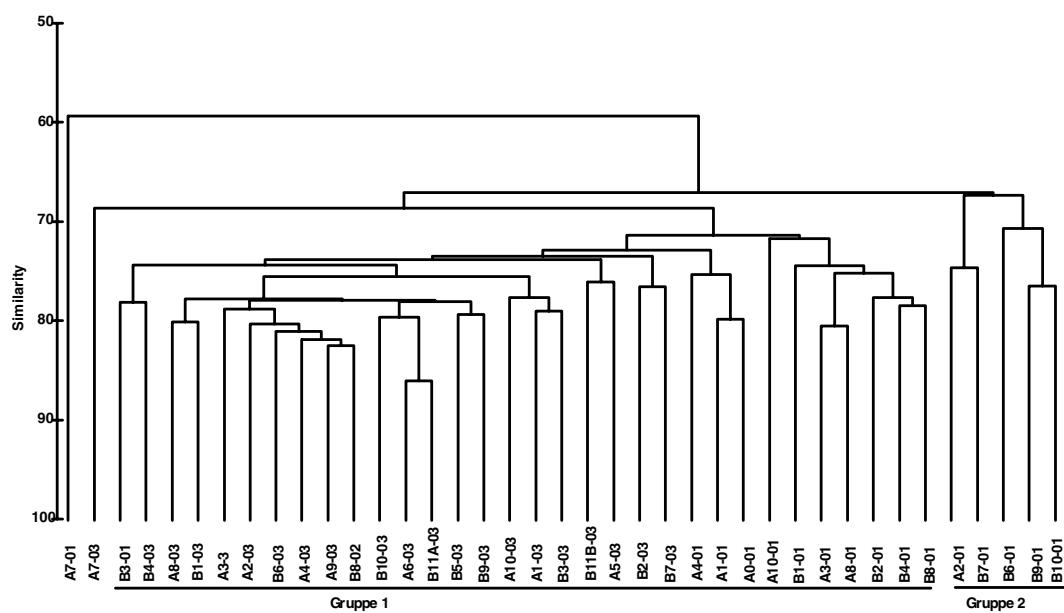

The results from the similarity analysis could indicate an incipient slight disturbance in the fauna. However the diversity indices are high and the differences could be random and natural or be due to slight differences in the sediment structure.

A bioenv analysis gave a correlation of 0,5 between fauna and a combination of the factors Cu and gravel. The single factor that correlated best (0,5) was gravel. This is not any good correlation, but could indicate some relation.

In figure 4.17 the dendrogram for the years 2001 and 2003 is given. The stations divide into 2 main groups at a similarity of about 70 %, independent of years. It has been an increase in the number of individuals at some stations since 2001.

Table 4.28. Depth, number of species (S) and number of individuals (N) per $0,5\text{ m}^2$, Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES_{100} , Mikkel 2003.

4.10 Rogn south

4.10.1 Grain size and chemical analysis

The sediments at Rogn Sør consist of very fine sand to fine sand. The content of silt and clay varies from 33,4 % at station ROGNS-08, 200°/250m to 60,4 % at station ROGNS-04, 30°/2000m. Gravel is found at all stations, except one, up to 23 %. Only small differences from the baseline survey in 2001 are observed.

The total organic matter content in the sediments varies from 2,3 % at the reference station ROGNS-15, 290°/4000m to 4,0 % at station ROGNS-10, 200°/1000m. The values are similar to the 2001 results.

The THC concentrations are low and vary from 2,1 mg/kg at the reference station ROGNS 15A, 290°/4000m to 11,1 mg/kg at station ROGNS 11, 290°/250m. Slightly elevated values are only found at one station at 250m in 290° direction, an increase since 2001.

The concentrations of NPD and PAH are low, and elevated values are not found. Decalins are not found either.

The Ba concentrations are low and vary from 99 mg/kg at station ROGNS 04, 30°/2000m to 314 mg/kg at station ROGNS 11, 290°/250m. Slightly elevated values are found at three stations, an increase since 2001. These are stations ROGNS 08, 200°/250m, ROGNS 11, 290°/250m and ROGNS 12, 290°/500m.

The concentrations of the heavy metals are low, and only some elevated values are found.

The chemical results are in agreement with the drilling history. The drilling at Rogn Sør started in 2002 with drilling of 2 wells with water based drilling mud. 1 m³ of the base oil EDC 95-11 has been discharged. Baryte has not been discharged.

4.10.2 Biology

The fauna at Rogn Sør could be characterised as very divers and undisturbed. Comparable regional stations do not differ from the Rogn Sør stations.

The Shannon-Wieners diversity index (H') range from 5,6 (ROGNS-03 and 04 in direction 30°/1000–2000m and ROGNS-11 (290°/250m) to 6,1 (ROGNS-15A, 290°/4000m). Pielou's index of evenness was high (0,9) at all stations.

Different fauna parameters are given in table 4.31.

The MDS plot from the similarity analysis at station level is given in figure 4.18. The stations divide into 4 main groups at about 60 % similarity. The stations in group 3 are further divided into 2 sub groups at a similarity of about 70 %. Station ROGNS-03 in group 4 differs somewhat from the rest of the stations in the group.

The analysis could indicate a somewhat greater supply of organic material at the stations in 250–550 m distance from the field centre. In addition the stations ROGNS-7 and 14, which are localised respectively 110°/1000m and 290°/2000m in direction and distance from the field centre, grouped together with these stations. However the diversity indices are very high and the fauna must be characterised as undisturbed. A bioenv analysis gave a correlation of 0,5 between fauna and grain size, which indicate some relation.

In figure 4.19 the dendrogram for the years 2001 and 2003 is given. The analysis shows a great resemblance between the years 2001 and 2003 (about 70 %). It is mainly a higher numbers of individuals in group 2 (2003) within the family Ampharetidae (mainly *A. macroglossus*) which contributes most to the difference. There are small differences within other families between the years. *A. macroglossus* is a suspension feeder and is relative sensitive. The difference between the years is small and is probably random and natural.

Table 4.31. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Rogn Sør 2003.

4.11 Kristin

4.11.1 Grain size and chemical analysis

A baseline survey at Kristin is performed which includes 39 stations arranged on four templates. The sediments consist of very fine sand. The silt and clay content varies from 38 % at station KR7, 240°/500m to 52 % at station KN7, 240°/1000m. Gravel is found at most of the stations, up to 6 % at station KR7.

The total organic matter content is very similar over the field, and the concentrations vary from 2,3 % to 3,6 %.

The THC concentrations are low across the field, the lowest THC concentrations found at Region VI. Slightly elevated values are, however, found at one station, station KP9, 330°/1000m with 6,9 mg/kg and hydrocarbons similar to drilling mud base oil. At the other stations the THC concentrations vary from 1,6 mg/kg at station KN1, 150°/500m to 2,9 mg/kg at station KS5, 60°/1000m.

The concentrations of NPD and PAH are low, and elevated values are not found. Decalins are not found.

The Ba concentrations are low across the field except for one station, KS10, 330°/1000m with 1370 mg/kg. The Ba concentrations vary from 89 mg/kg to 1370 mg/kg. Slightly elevated Ba values are found at 9 stations out to 1000m from the templates, two at template P, two at template R and five at template S. The concentrations of the heavy metals are low, and elevated values are not found.

4.11.2 Biology

The diversity indices indicate a very healthy fauna community in the area.

The Shannon-Wieners diversity index (H') range from 5,3 (KR-01) to 6,1 (KSRefB). Pielou's index of evenness was in general high and range from 0,8 to 0,9.

Different fauna parameters are given in table 4.33.

The similarity analysis, see MDS plot in figure 4.20, divided the stations into 2 main groups at about 65 - 70 % similarity. Most of the stations group in group 1 at a similarity of 70 %. The bioenv analysis gave a correlation of 0,5 between fauna and a combination of the factors depth, Cd, organic material and grain size. The correlation factor suggests some relation.

The results from the similarity analysis of Kristin with comparable regional stations, show a higher numbers of indicator species at Kristin.

Table 4.33. Depth, number of species (S) and number of individuals (N) per 0,5 m², Shannon-Wieners diversity index (H'), Pielou's index of evenness (J) and ES₁₀₀, Kristin 2003.

na: not analysed nd: not detected

Quantification limit decalins: 0,05 mg/kg

NPD, PAH, decalines and Hg are not analysed on all stations

5.1.1 Grain size distribution

The sediments at Region VI are partly dominated by silt & clay and partly of very fine sand. Mikkel differs from the other fields and show a great variation, from silt and clay to coarse sand. At the regional stations the silt and clay content varies from 57 % at Regional 9 (in the western part of Region VI) to 92 % at Regional 1 (north in Region VI close to Norne). The lowest mean content is found in the middle of the region at Åsgard N, 39 %, and the highest content is found at Norne, 90 % at Norne NW and 80 % at Norne SW. The remaining fields have a mean content of silt and clay from 41 % to 73 %. Gravel is found at most of the stations.

At most of the fields the results from the present survey at Region VI are similar to the results from the previous survey in 2000. However, some changes are observed. At Norne a considerable increase is found in the silt and clay content at one of the 250m stations, from 61 % to 96 %. At Draugen an increase at some stations and a decrease at other stations are observed.

5.1.2 Total organic material (TOM)

The total organic matter content in the sediments is relatively high. The variation at the region is in accordance with the grain size distribution. The lowest content, 1,7 %, is found at one of the 500m stations at template A at Mikkel. The highest content, 8,1 %, is found at one 500m station and one 1000m station at the Norne NW template. The results correspond to the results from the previous environmental survey in 2000.

5.1.3 Hydrocarbons

The hydrocarbon content in the sediments that originates from the drilling mud base oil or base liquid, depends on the drilling history, and will thus vary from field to field.

At the regional stations and the additional reference stations the THC concentrations are low, and they vary from 2,6 mg/kg to 4,7 mg/kg. No increase is observed since the last survey in 2000.

Two baseline surveys are performed in 2003, at Garn Central in the Draugen area and at Kristin situated west of Åsgard. As expected the THC concentrations in the sediments are low. The THC concentrations at Garn Central vary from 3,1 mg/kg to 5,6 mg/kg and at Kristin from 1,6 mg/kg to 6,9 mg/kg.

The THC concentrations are also low at Draugen, Garn Vest, Rogn Sør and Åsgard installations N and X. At Draugen the THC values vary from 2,6 mg/kg to 5,1 mg/kg, a decrease since 2000, and elevated concentrations are not found. At Garn Vest and Rogn Sør a slight increase is found since the baseline surveys, and only one 250m station at each field shows slightly elevated concentrations, 8,2 mg/kg and 11,1 mg/kg respectively. At Åsgard N and X slightly elevated THC concentrations are also found at one station at each template, 14,9 mg/kg and 9,8 mg/kg respectively.

The THC concentrations are somewhat higher at Norne and Åsgard S, although all values are below 50 mg/kg. The concentrations are decreased since 2000, and the highest concentrations found are 18,5 mg/kg at Norne SW, 25,7 mg/kg at Norne NW and 40,2 mg/kg at Åsgard S.

At Åsgard M, Heidrun and Mikkel A and B the highest THC concentrations are between 52 mg/kg and 112 mg/kg. Template M at Åsgard has not been included in the previous surveys, and elevated THC concentrations are found at two of the four 500m stations.

At Heidrun an increase is found at several stations at 500m, and elevated concentrations are found at most of the stations at the main field, that is out to 1000m. It is likely that some of the elevated THC level at Heidrun results from drilling mud base oil, and that the main part of the THC contamination results from other discharges. At Mikkel the THC concentrations are increased since the baseline survey in 2001, however, THC concentrations above 10 mg/kg are only found at two stations, one at 250m (template A) and one at 500m (template B).

High THC concentrations are found at Njord, up to 3660 mg/kg. This very high THC level, more than 3000 mg/kg, results from leakage of oil based mud from *slipjoint* in 2000, and degradation of this oil will takes time. The THC values are increased at the two innermost stations in the 67,5° direction since 2000, otherwise the levels are the same or they are decreased. Station NJ6, 157,5°/500m differs from the other stations as a more fresh "drilling mud base oil" is found in the sediments. The station inside, NJ5, 157,5°/250m, does not show the same hydrocarbon profile, but has a more common profile of degraded "drilling mud base oil". The results indicate acute discharges in the neighborhood of NJ6. Drilling mud base oil is found out to 2000m.

A vertical transport of hydrocarbons in the sediment layers is observed. The concentrations are lower than in the top 0-1 cm layer.

The concentrations of the selected hydrocarbons NPD and PAH are low at Region VI, while a great variation in the concentrations of C₅ - C₈ alkyl decalins is observed. Decalins are not found at the regional stations, Draugen, Garn Vest, Garn Central, Rogn Sør and Kristin. At Norne, Åsgard, Heidrun and Mikkel decalins at mg level are found, while up to 265 mg/kg is found at Njord. A good correlation between the decalin results and the THC results is obtained. The presence of decalins gives indication of drilling mud base oil in the sediments. The base oils HDF 200 and EDC 95-11 both contain a few % of C₅ - C₈ alkyl decalins.

Generally the THC results are in agreement with the drilling history.

5.1.4 Esters

Esters from the drilling fluid Petrofree are only analyzed at Heidrun. Petrofree is not found in the sediments, and esters were not found in the 2000 survey either.

5.1.5 Ethers

Ethers from the drilling fluid Aquamul B II are only analyzed at Heidrun in the TLP area. Aquamul B II is found at all stations, up to 65 mg/kg at one of the 550m stations. At another 550m station a gradually decrease is found, from 271 mg/kg in 1997, 119 mg/kg in 2000 to 17,9 mg/kg in 2003. Generally the conclusion is status quo, and the results confirm the slow degradation rate of the drilling fluid Aquamul B II.

5.1.6 Barium

Ba is found in the sediments due to use of barite during drilling with water based drilling mud, oil based drilling mud or pseudo-oil based drilling mud as well. Thus higher concentrations of barium in the sediments and greater dispersal area will be found compared to hydrocarbons.

The Ba concentrations vary from background levels to 8100 mg/kg, and the results are in agreement with the previous survey in 2000.

As for THC a vertical transport of Ba in the sediment layer is observed, lower concentrations than in the upper 0-1 cm layer.

At the regional stations and the reference stations the Ba concentrations are low, and they vary from 88 mg/kg to 182 mg/kg.

Elevated Ba concentrations are found at most of the stations at the older fields. This means out to 1000m at Garn Vest and out to 2000m at the other fields. At Rogn Sør elevated Ba concentrations are only found at three stations, out to 500m. At Kristin, a baseline survey, elevated Ba concentrations are found at 9 of 39 stations, out to 2000m as well.

The Ba level is generally as previously. However, some decreases are found at Draugen, and some increases are found at Norne, Heidrun, Garn Vest, Mikkel and also at Njord.

5.1.7 Metals

Generally low concentrations of the heavy metals are found in the sediments. To our opinion, the concentrations found are mainly within the natural levels at Region VI. Only a few elevated levels are found for Cr, Cu, Pb and Zn. Cr varies from 15 - 44 mg/kg, Cu varies from 3 - 40 mg/kg, Pb varies from 7 - 66 mg/kg and Zn varies from 24 - 149 mg/kg. In addition high Cu concentrations, 154 mg/kg, are found at one of the 500m stations at Mikkel template A.

Cd and Hg are found at all fields, 0,04 to 0,11 mg/kg for Cd, and 0,01 to 0,07 mg/kg for Hg. The levels are low and correspond to the results from 2000. A relatively high Hg concentration, 0,30 mg/kg, is found at one of the 500m stations at Heidrun.

5.1.8 Limit of significant contamination

Based on the content of THC, NPD, PAH, Ba, Cr, Cu, Pb and Zn in the sediment there is calculated a limit of significant contamination, a LSC value (limit of significant contamination). Concentrations above this limit can be viewed as higher than background levels or a pollution of the sediments.

The LSC value is calculated by using a one tailed t-test with confidence limits of 95 %. Data from the regional and reference stations from the period 1996 – 2003 are used. The calculations of THC and Ba are bases on 155 measurements.

LSC values for this year investigation are presented in table 5.2. The values are for the whole region and are mg/kg dry sediment.

Table 5.2. LSC values (limit of significant contamination), Region VI 2003.

Parameter	LSC 2003 mg/kg 95 % confidence level
THC	5,3
Ba	198
Cr	33
Cu	12
Pb	25
Zn	60
NPD	0,101
PAH	0,143

5.1.9 Polluted/contaminated area

When evaluating which stations have increased THC values and thereby are polluted by hydrocarbons, both the THC content and the gas chromatogram that shows the hydrocarbon profile are used. Especially we look at the retention area for the drilling mud oil HDF 200, and if there is any extra "peaks" compared to the sample from the reference station

Base on stations with increased values, the extent of the polluted area is decided. In those cases where there is not enough data to decide the extent of the THC pollution, we have to make an estimate.

In table 5.3 an overview of the basis for the calculations at each field are presented.

Table 5.3. THC pollution, Region VI i 2003.

Field	Direction	Distance	Comments and THC concentrations in mg/kg
Norne NW	135°	< 500m	250m station is not analysed
	45° og 315°	250 - 500m	Only the 500m station show traces of THC. Probably limit between 250m and 500m
	225°	some > 500m	17,1 at 500m, no THC at 1000m
Norne SW	135° og 315°	500m	8,2 and 8,8 at 500m, no THC at 1000m
	20°	700m	8,8 at 700m, no stations further out
	225°	1000m	6,2 at 1000m, clear THC "peak" in one grabb. No stations further out.
Åsgard N	60°, 150°, 330°	< 500m	Only 500m stations are analysed at N
	240°	some >500m	14,9 at 500m
Åsgard S	30°, 160°, 250°	< 500m	250m station is not analysed
	75°	500m - 1000m	40,2 at 500m, no THC at 1000m.
Åsgard X	90°, 225°, 315°	< 500m	Only 500m stations are analysed at X
	45°	500m	9,8 at 500m
	145°, 325°	< 500m	Only 500m stations are analysed at M
Åsgard M	60°	> 500m	75,5 at 500m
	240°	500m	7,0 at 500m
	225°	550m - 1000m	36,1 at 550m; no THC at 1000m
TLP	305°/315°	some > 550m	12,5 at 550m; no THC at 1000m
	45°/50° og	1000m	9,2 and 9,1 at 1000m; no stations further out.
	120°/135°		
Bunnrammer	135° og 315°	< 500m	250m station is not analysed.
	30°/35°	some > 500m	15,0 at 500m, no THC at 1000m
	225°	500m	8,3 at 500m; no THC at 1000m
Draugen	300°	< 250m	Boundary is difficult to understand because there is only one 250m station (300°).
	162° og 325°	< 500m	
	45°	< 750m	
Garn Vest	30° og 210°	0 - 250m	Only traces of THC at 250m station, 6,3 and 6,8
	120°	250m	8,2 at 250m, no THC at 500m
Garn Central	30°, 120°, 210°	< 250m	No stations have increased THC values. The field is not polluted by THC
	og 300°		
Njord	22,5° og 247,5°	1000m	11,1 and 8,9 at 1000m, not THC at 2000m
	112°	1000m - 2000m	28,0 at 1000m, no THC at 2000m
	67,5°, 157,5° og	2000m	7,7; 7,2; 6,4 at 2000m
	337,5°		2000m is the outermost station in all directions

	110°	< 500m	250m station is not analysed.
	290°	250m	11,1 at 250m, no THC at 500m
Kristin	60°, 150°, 240°	< 250m	Increased values of drilling mud oil is found at one station, KP9 330°/1000m (6,9 mg/kg), no increased values inside. The field is not polluted by THC.
N, P, R og S	og 330°		

The area contaminated by THC (higher than LSC value on 5.3 mg/kg) is calculated to be greater than 25 km². For some fields the outermost station in one of the axes is contaminated in accordance with the LSC value, something that makes it difficult to exactly estimate the contaminated area. In those cases where the 500m station is contaminated and not the 1000m station, the area of contamination is set to the average distance of 750m. The area calculations are based on the calculations shown in table 5.4, which show the distance out from four axes where increased concentrations of THC is found (> LSC values).

In figure 5.1 an isoline plot for THC and Ba concentrations for all stations shown.

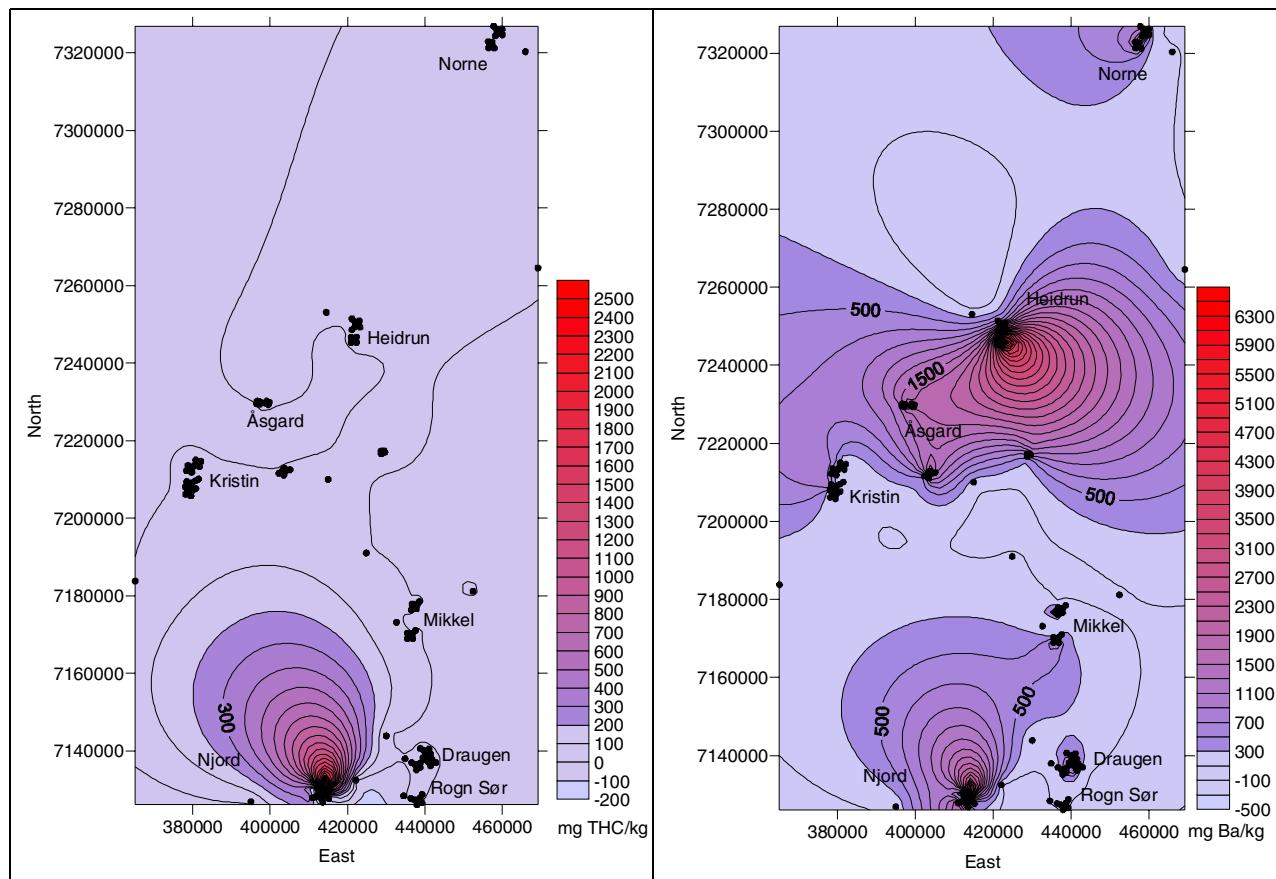

Figure 5.1. Iso plot for the THC concentrations to left and the Ba concentrations to the right. Due to locally heighten concentrations of THC, the resolution in the plot is difficult to illustrate. In total the THC contaminated area is calculated to be over 25 km². Barium is dispersed over a larger area and the total area with concentrations above 198 mg/kg is calculated to be over 100 km².

Table 5.4. Basis of calculation for THC contaminated area, Region VI Haltenbanken 2003.

Installasjon	Akse 1 (m)	Akse 2 (m)	Akse 3 (m)	Akse 4 (m)	Radius	Areal (km ²) > 5,3 mg THC/kg	Andel

Kristin S	250	250	250	250	0,2500	0,20	1 %
						24,97	

The area is calculated in accordance with an LSC value on 5,3 mg/kg corresponds to 25 km², which is some higher than in 2000, where the contaminated area was calculated to 20 km². In 2000 the LSC value was 6,0 mg THC/kg.

Barium is used as an indicator of discharge and all stations around the installations is regarded as polluted. The actual area is greater than estimated here because the outermost stations have higher concentrations than the LSC value of 196 mg Ba/kg. A minimum of 100 km² is contaminated by barium. In 2000 the area was minimum 68 km², calculated from a LSC value of 220 mg Ba/kg. This means that the area has increased some since 2000.

In table 5.5 an overview of the area contaminated by Ba is shown.

Table 5.5. Basis of calculation for the estimation of Ba contaminated area, Region VI Haltenbanken 2003.

5.1.10 The influence on the bottom fauna

The dendrogram shown in figure 5.3 shows that some of the stations at Njord is most different from the other stations in the region. Some stations at Heidrun and one station at Draugen are also different from the other stations in the region. The remainder of the stations in the region separates at approximately 55 % similarity. The stations are generally separated according to field, and the most homogeneous fields were Norne, Kristin, Mikkel and Draugen.

The calculations of how great area which is influenced is performed as follow:

An index based on the average values from the reference and regional stations minus 2 * standard deviation is worked out (intercept stations which are low/moderate polluted). This index is compared to the results from the multivariate analysis. If there is not shown any influence on the innermost station the “area contaminated” is still regarded limited by the innermost station (in most cases 500m, but 250m at some fields). This means that the calculations have to be interpreted as less than the given area. In those cases where there is shown increased levels at 500m but not at 1000m, the area is calculated from an average distance at 750m.

Average diversity index for the regional and reference stations was 5,7. The limit value then become 5,2 when subtracting 2 * standard deviation. Based on this, 6 out of 22 stations at Njord are disturbed, 5 out of 19 at Heidrun and 1 station at Åsgard. At Norne we can not use the same reference value because of the special bottom type.

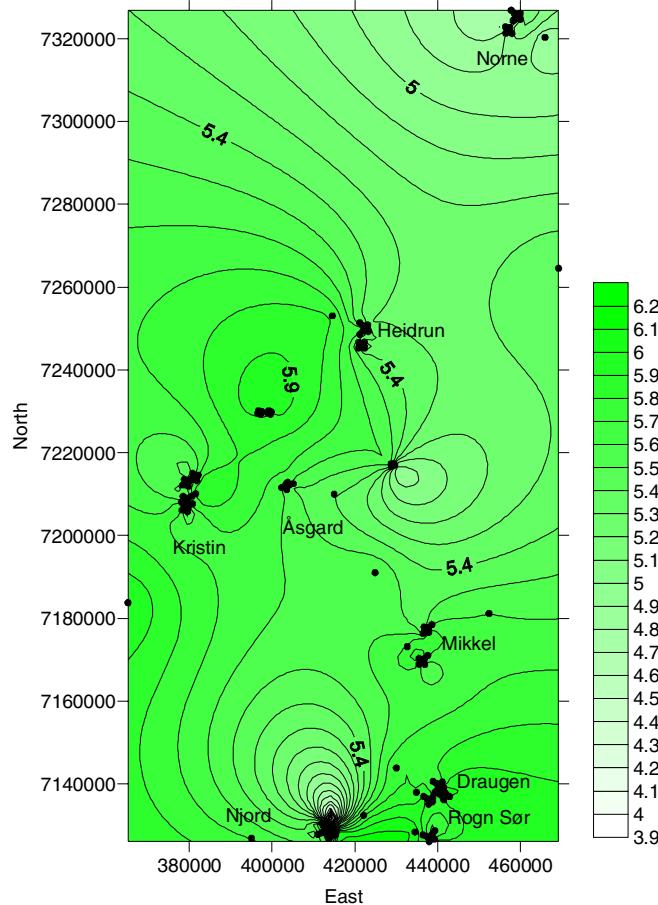

Estimated area becomes almost the same. In table 5.6 is the calculations shown. Influenced area is less than 10 km² for the whole region.

Table 5.6. Calculations of influenced area a) based on diversity b) based on multivariate methods.

A) Field	Axis 1 (m)	Axis 2 (m)	Axis 3 (m)	Axis 4 (m)	Radius	Area (diversity)

TOTALT						11,7 km ²

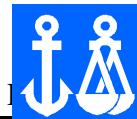

ENGLISH SUMMARY

Figure 5.2 shows that the diversity is high in the whole region. The area which is slightly disturbed or influenced is limited to less than 10 km².

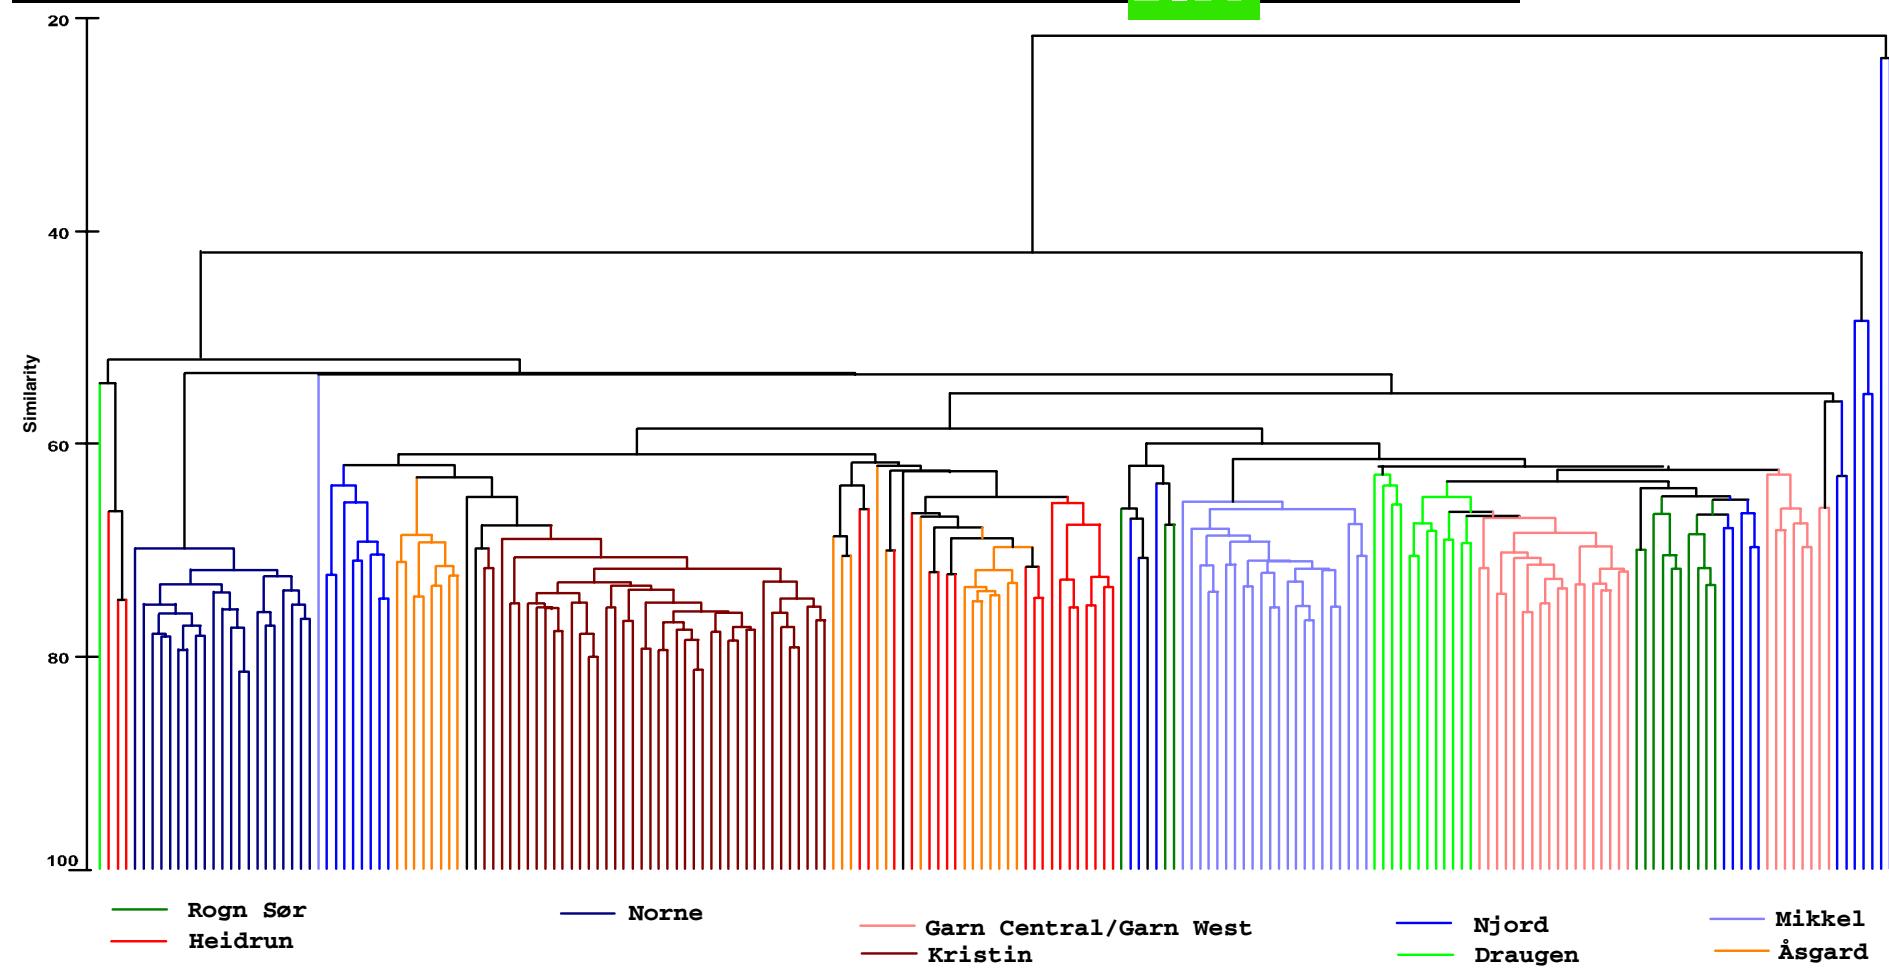

Figur 5.2. Isoline plot - diversity in the region.

For several fields the analysis and species composition indicated an increased supply of organic material, both between areas and over years, which in several cases can not be related to the activity in the area. Compared to last investigation the results generally show an increase the number of individuals. This could be random changes in time and space but may also imply a general increase of organic material to the region.

ENGLISH SUMMARY

Figur 5.3. Dendrogram for all stations in Region VI – Haltenbanken 2003

5.2 Conclusions – Region VI

The environmental investigation in 2003 at Region VI has given these results:

The 2003 survey at Region VI shows:

- The sediments at Region VI are partly dominated by silt & clay and partly of very fine sand.
- The total organic matter content in the sediments is relatively high and varies from 1,7 % to 8,1 %.
- The chemical results are in agreement with the drilling history.
- The regional stations and the reference stations are still unaffected by the drilling chemicals - no contamination or elevated concentrations are found in these sediments.
- Relatively high THC levels (>50 mg/kg) are found at Åsgard M, Heidrun, Njord and Mikkel. The THC concentrations are lower at Norne, Åsgard N, S and X, Garn Vest and Rogn Sør, and elevated THC levels are not found at Draugen, Garn Central and Kristin. The dispersal area varies, out to 250m from the installation at new fields to 2000m at Njord. The THC concentrations have increased at Heidrun, Mikkel and partly at Njord. At Njord one station still contains very high THC concentrations due to leakage of oil based drilling mud from *slipjoint* in 2000.
- Decalins are found in the sediments when drilling mud base oil is found.
- Olefins and esters from drilling fluids are not found in the sediments at Heidrun.
- Ethers from the drilling fluid Aquamul B II are found in the sediments at Heidrun, the same low concentrations as in 2000. The results indicate a slow degradation rate.
- Dispersion of drillcuttings and mud is illustrated by the barium results. Elevated Ba concentrations are found out to 500m at Rogn Sør, out to 1000m at Garn Vest and out to 2000m at the other fields. Generally the Ba concentrations are similar to previous surveys, however a decrease is found at Draugen and an increase is found at Norne, Heidrun, Garn Vest, Mikkel and partly at Njord.
- The concentrations of the heavy metals are low, and elevated levels are only found at some stations.
- The results from the present survey in 2003 are in agreement with the 2000 survey.
- The macro benthic fauna community in the region are in general healthy and undisturbed. The species composition at the Regional station 1 and 3 differ somewhat from the other Regional stations. At these stations there are a relative fine sediment compared to the others. Analyses over year show that there have not been any considerable changes in the region in the period 1997 – 2003.

- Following stations are considered as disturbed:
 - Station Heidrun-6 (50° /550m) together with Heidrun-7 (45° /1000m) and Heidrun-12 (120° /550m). There was a good correlation between fauna and a combination of the factors Ba, Cd, Pb og THC.
 - Station DR24B (300° /250m) at Draugen was characterised as disturbed in 2000, and the analysis reveals that this is still the case. But the levels of Ba and THC are reduced since 2000.
 - At Njord the stations NJ-6 ($157,5^{\circ}$ /500m) and NJ-13 ($337,5^{\circ}$ /250m) are disturbed. In addition the analysis indicate slightly disturbance in the fauna at the stations NJ-9 ($247,5^{\circ}$ /250m), 14 ($337,5^{\circ}$ /500m), NJ-1 ($67,5^{\circ}$ /250m), NJ-2 ($67,5^{\circ}$ /500m) and NJ-5 ($157,5^{\circ}$ /250m).
- At several fields in the region, changes in the species composition gives indications of an increased supply of organic material.
- The results from the present survey in 2003 are in agreement with the 2000 survey.

6 RECOMMENDATIONS

New stations

It is recommended to consider including new stations in the survey, particularly close to the installations (250m). At region VI several 500m stations have no elevated THC concentrations, and this may lead to uncertainty in the calculation of the contaminated area.

Establishment of LSC values (limit of significant contamination)

At Region VI environmental surveys have been performed in 1997, 2000 and in 2003. This means that a great many data exist for the different parameters. In the present calculation of LSC values, the numbers are based on 155 data for THC and for Ba as well.

It is recommended to consider if sufficient data now are available to establish fixed LSC values for the chemical parameters at Region VI.

It is also recommended to consider to use a confidence level of 99 % in the calculations instead of 95 %, to get realistic LSC values. The LSC value should not be lower than the natural backgroundlevel at the region.
